MINICH, J. A., M.D., Worthington, Ind.
MOLLENHAUER, R., M.D., New York City.
MORRIS, G. G., M.D., Washington, D.C.
MUSGROVE, CHARLES W., M.D., Austinville, Pa.
MUSSER, J. H., M.D., Philadelphia.

NOBLE, CHARLES P., M.D., Philadelphia.

PACKARD, FREDERICK A., M.D., Philadelphia.
PARKER E. H., M.D., Poughkeepsie, N. Y.
PARVIN, THEOPHILUS, M.D., Philadelphia.
PENROSE, CHARLES B., PH.D., M.D., Philadelphia.
PEPPER, WILLIAM, M.D., Philadelphia.
PERSINGER, E. I., M.D., Campti, Louisiana.
PETER, PROF. M., Paris, France.
PRICE, MORDECAI, M.D., Philadelphia.

RANSLEY, A. W., M.D., Philadelphia.
RECORDS, B. F., M.D., Smithville, Mo.
REID, JOHN J., M.D., New York City.
RIDLON, JOHN, M.D., New York City.
ROBBINS, HONORA A., M.D., Bloomsburg, Pa.
ROBERTS, A. SYDNEY, M.D., Philadelphia.
ROBERTS, JOHN B., M.D., Philadelphia.
RORER, MRS. S. T., Philadelphia.
RUNNALLS, H. B., M.R.C.S. Eng., Bedford Springs, Pa.

SCOTT, T. Y., M.D., Bentleyville. Pa.
SEGNITZ, B., M.D., New York City.
SHEPARD, C. S., M.D., La Porte City, Iowa.
SCHMIDT, JOSEPH, M.D., Berlin, Germany.
SCHÜLLER, MAX, PROF., Berlin, Germany.
SCHWARTZ, N. F., M.D., Shanesville, Ohio.
SHARPLES, CASPAR W., M.D., Philadelphia.
SHIVERS, C. H., M.D., Haddonfield, New Jersey.
SHOEMAKER, GEORGE ERETY, M.D., Philadelphia.
SHULTZ, R. C., M.D., New York City.
SMITH, B. M. JR., M.D., Parsons, West Va.
STUBBS, H. J., M.D., Wilmington, Del.
SWAN, J. M., M.D., Canton, China.

TODD, WILLIAM C., M.D., Roxborough, Pa.
TOWLER, S. S., M.D., Marienville, Pa.
TRENT, I. N., M.D., Columbus, Ohio.
TULL, M. GRAHAM, A.M., M.D., Philadelphia.

VANDERBECK, C. C., M.D., San Francisco, California.
VANDERPOEL, E., M.D., New York City.

WALKER, JAMES B., M.D , Philadelphia.
WARD, STANLEY M., M.D., Scranton, Pa.
WHITE, J. WILLIAM, M.D., Philadelphia, Pa.
WILLARD, DE FOREST, M.D., PH.D., Philadelphia.
WILLIAMS, CHARLES B., M.D., Philadelphia.
WILLIS, H. F., M.D., Preston, Md.
WILSON, JAMES C., M.D., Philadelphia.
WOOD, H. C., M.D., Philadelphia.
WOODRING, CHARLES P., M.D., Meadville, Pa.

YOUNG, JAMES K., M.D., Philadelphia.

INDEX.

Abasia following poisoning with carbonic oxide, 531.
Abdominal diseases, plea for prompt interference in, 701.
Abdominal pálpation, technique of, 168.
Abdominal section, one thousand consecutive cases of, 140; complications following, 420, 425.
Abortion, with placenta previa, 376.
Abortionists, criminal, punished, 585.
Abscess, of both testicles from urethral and prostatic obstruction, 115; of vertebræ, 633.
Acaciæ, mistura, 346.
Acetized cotton, 266.
Acetonuria, relation of diabetic coma to, 114.
Acid, lactic, in tubercular diarrhœa, 139.
Acids, effects of, on stomach, 143.
Acne, treatment without arsenic, sulphur ointments, or lotions, 573.
Acting Assistant Surgeons U. S. Army, Association of, 95.
Actinomycosis, three remarkable cases of, 368; 688.
Adenitis, chronic cervical, surgical treatment of, 253.
Adler, Lewis H. Jr.—Amputations at the Hospital of the University of Pennsylvania from Sept. 30, 1874, to Dec. 31, 1888, 570; stricture of the rectum probably from specific vaginitis, 757.
Agnew, Professor, farewell of, 467.
Albuminuria and yellow fever, 347.
Albuminuria of pregnancy and puerperal eclampsia, 206.
Alcoholism, chronic, 457; pathology of chronic, 548.
Alexander's operation, Prof. Polk on, 201.
Allopathy, 346.
Alopecia areata, 466.
Amber beds, new, near Dantzig, 378.
"American College of Health and Vitapathic Institute," 159.
American Medical Association, 287.
American Physiological Association, 348.
Ammonium chloride in fumes for inhalation, 557.
Amputation, simultaneous of both arms; recovery, 605.
Amputations of thigh and leg, 135, 232; at the University Hospital during fourteen years, 570.
Anæmia, bichloride of mercury in, 754.
Anæsthesia, formula for producing local, 95.
Anæsthetic, bromide of ethyl as an, 670.
Anæsthetics, 289.
Anatomical tubercle, 95.
Anders, J. M.—Ventilation of cities, 731.
Anemone pulsatilla in gonorrhœal orchitis, 285.
Aneurism and epilepsy, 667.
Aneurisms of aorta, treatment, 689.
Angina pectoris, cocaine in, 379.
Anthrax in swine, 24.
Antifebrin, case of poisoning with, 725.
Antipyretics, action of, 576.
Antipyrin, idiosyncrasy as to, 94; poisoning with, 126; mode of action of in typhoid fever, 138; in labor-pains, 153; in obstetric practice, 220; for renal calculus, 518; phenacetin and, 615.
Antisepsis and the country physician, 136.
Antiseptics in normal labor, 734.
Antrum of Highmore, diseases of, 615.
Army Medical Board, 441.
Arrow poisoning, Mr. Stanley on, 744.
Arsenic poisoning, singular results of, 204.
Arsenical poisoning, chronic, from wall-paper, 367.
Arthralgia, hysterical traumatic, 137.
Arthrectomy of the knee-joint as a substitute for excision, 510.
Arthritis, chronic rheumatic, 337; commencing, 574.
Aseptic surgery, 261.
Ashhurst, John Jr.—Arthrectomy of the knee-joint as a substitute for excision, 510.
Assault, is communication of infection an, 30.
Asthma, caused by a foreign body, 162; euphorbia pilulifera in, 319; unusual cause of, 370.
Athletic sports and gymnastics at the University of Pennsylvania, 379.
Athletic sports and scholarship, 223.
Atropine for prevention of shock, 557; in opium poisoning, 740.
Australia, letter from, 176.

Baldness, treatment of, 218.
Baldy, J. M.—Complications following abdominal section, 420; plea for prompt interference in abdominal diseases, 701.
Ballou, W. R.—Replacement of button of bone after trephining, 198.
Barr, G. W.—Antisepsis and the country practitioner, 136.
Barton, J. M.—Digital dilatation of the pylorus, 443.
Base-ball, fatal injury from, 755.
Basham's mixture, formula of, 346.
Battey's operation, 657.
Baum, Charles.—A case of meningocele, 265, 346.
Beall, E. J.—Fibro-cystic tumor of the uterus; unusual treatment; cure, 1.
Bedford Springs as a health resort, 199.

Belladonna in whooping-cough, 753.
Benjamin, D.—Hysterectomy for large fibromyoma, 681.
Berlin, letters from, 81, 203, 659, 686, 764.
Bill, a large, 754.
Biniodide of mercury, its antiseptic use, 267.
Bishop, Mr., 699.
Bismuth, characteristic reaction of, 251.
Bisulphide of carbon poisoning, 354.
Bladder, photography of the male, 55; pin in, 137; stone in, 432; absorbent power, 654; reconstruction of a, 658.
Blennorrhœa in women, 399.
Bone, artificial stimulation of growth of, 406.
Boro-glyceride, formula, 556.
Bouchard, Prof.—Practical value of the knowledge of pathogeny, 617.
Bougies, nasal, 146.
Brain, lacerated wound of, 23; tumor of and accidental injury, 208; softening of from thrombosis, 498; cortical motor region, Horsely on injuries of, 686; tumor of, 761.
Brazil, yellow fever in, 667.
Bright's disease, 308.
British and American Continental Medical Society, 215.
Bromide of ethyl as an anæsthetic, 670.
Bromide of sodium for quinine idiosyncrasy, 614.
Bromine (*see* Deodorant, new).
Broncho-pneumonia, 273.
Bruen, Edward T.—Nervous dyspepsia, 413.
Bryonia alba in hemorrhage, 526.
Buboes, treatment of, 587.
Bucklin, C. A.—Obstruction of the nasal passages, 589.
Burlington, Vermont, chair of surgery at, 586.
Burn Brae vindicated, 55.
Burns, salol in, 527; extensive, pathological anatomy, 715.
Burr, William H.—Influence of stomach digestion in the production of heart failure, 384.
Butter, analysis of, 613.

Cæcum, extirpation, 631.
Cæsarean section, 612.
Cæsarean section for carcinoma of the cervix uteri, 381.
Caffeine, citrate of, poisoning with, 348.
Calculus, in British Islands, 210; renal, antipyrin in, 518.
Camphoric acid in catarrhs of mucous membranes, 285.
Cancer, of larynx, frequency of, 116; of womb, in a girl eight years old, 145; of breast, cocaine in, 250; and syphilis, combination of, 253; good caustic for, 274; of breast, removal, 574; causes of relapse in, 687; prevention of relapse, 687.
Carbonic oxide, abasia following poisoning with, 531.
Carcinoma, 336; Esmarch on, 686; inoculation of, 688.
Cardiac injuries, fatality, 729.
Cardiac rhythm, significance, 743.
Cards, doctors', good form in, 151.
Caries, spinal, treatment, 453.
Carlsbad water, influence of, on the secretion of uric acid, 713.
Carmine, Nikiforow's, 253.
Carrell, J. B.—Jaborandi, 42; retained placenta, 197.
Cates, B. Brabson.—Sub-spinous luxation of the humerus, report of a case, 77.
Cement for ringing balsam mounts, 253.
Cephalohæmatoma, 234.
Cerebellar abscess, case, 489.
Cerebral and cerebellar hemorrhages, case, 450.
Cerebral grafting, 656.
Cerebro-spinal meningitis, prophylaxis in, 223.
Charcot, J. M.—Traumatic crossed spinal hemiparaplegia; poisoning with bisulphide of carbon, 351; abasia following poisoning with carbonic oxide, 531.
Children, over-pressure in, 409.
Chills, chronic, 586.
China, letter from, 711.
Chinese, color-sense and color-blindness among, 651.
Chloral hydrate, value of, 737.
Chlorate of potassium prescription, a dangerous, 559.
Chloroform administration, 433; as an internal remedy, 669.
Chlorosis and menstruation, relation, 549.
Cholera, treatment and prophylaxis of, 127.
Chorea, acute, with insanity, 139; in British Islands, 210; hereditary, 244; rare case, 395; major, with formation of fungi in pia mater, 410.
Chorion, hydatiform degeneration of, 201.
Chyluria, case of, 599.
Circumcision, ritual of, 528.
Civilizer, doctor as, 190.
Clairvoyant "physicians," 497.
Cleft-palate, treatment of, 78.
Clergyman's charges against physicians, 29.
Club-foot, treatment of, 274.
Cocaine in cancer of breast, 250; toxic effect of, 254; in angina pectoris, 379; poisoning, fatal case, 409; in teeth-extraction, 411; chronic poisoning, 496; in variola, 526; new, by synthesis, 690.
Cohen, S. S.—Case of chyluria, 599; an imaginary tænia, 759.
Colocynth poisoning, case, 498.
Color-sense and color-blindness among the Chinese, 651.
Conception, prevention of, 606.
Conjugal question, 10.
Conjugal state, the, 230.
Conjunctival sac, bacteriology and antisepsis of, 277.
Constipation, in children, 393; chronic, 457.
Consumption, pulmonary, climatic treatment, 227.
Contagious diseases, hospitals for in Tennessee, 191.
Contortionist, anatomy of, 440.
Cook County Asylum, 769.
Cornea, mercury-lanolin in certain affections of the, 670; grafting of a rabbit's on a human eye, 684.
Corrosive sublimate, poisoning after a surgical operation, 286; poisoning, how to avoid, 433; use of in laparotomies, 629.
Coryza, treatment of acute, 94.
Cough, reflex or so-called useless, 323.
Creasote in phthisis, 31; with cod-liver oil and saccharin, 379; in lung affections of children, 585; in pills, 752.
Crematory, the Hughes, 575.
Creolin, in eye diseases, 61; case of probable poisoning with, 93; experiments with, 517.
Crime, physiology and pathogenesis, 602.
Crothers, T. D.—Headache in inebriety, 357.
Croup, formula for, 174.
Cry, intra-uterine, after expulsion of waters, 110.

Curwen, John.—Crowded hospitals for the insane, 386.
Cyst, recurrent intraligamentary, 12; ovarian, 13; sebaceous of groin, 243; dentigerous, of antrum of Highmore; operation, 741.
Cystitis, formula for chronic, 50; chronic, 336; in women, 526; in women, treatment of chronic, 550.
Cysts, of nose, dermoid, 81; gas- of vagina, 276.

Da Costa, J. M. — Cerebral syphilis; asthma caused by a foreign body, 161.
Damien, Father, 217; death of, 643.
Dartmouth, hospital for, 726.
Davis, E. P.—Erysipelas of pharynx and face, 172.
Dean, G. R.—Two months in the hospitals of Philadelphia, 707.
Death, absolute signs of, 154.
Deekens. A. H.—Turkish bath, 105.
Delaware Bay, new quarantine station at entrance to, 726.
Dentifrice, antiseptic saccharin, 467.
Deodorant, new, 277.
Diabetes mellitus, long continued, 59; fallacies of some of the tests for sugar in. Remarks on diet and methods of treatment, 363; and tumors, 396.
Diabetic coma, relation of acetonuria to, 114.
Diabetics, a good bread for, 207.
Diarrhœa, non-inflammatory, 710.
Diller, Theodore.—Case of cerebellar and several smaller cerebral hemorrhages, 450.
Diphtheria, identity of scarlatina and, 36; treatment of with yeast, 81; treatment of by cauterization of the deposits, 82; Wachsmuth's treatment of, 205; origin of human, from a similar disease in birds, 244; oil of turpentine in, 257; in children, treatment of, 275; microbe of, 378; bacillus of, 379; treatment, 395; and measles, mode of transmission, 517.
Diphtheritic croup, intubation of the larynx in, 516.
Doctor's presence of mind, 525.
Dog-bite, case, 237.
Druggist censured, 348.
Druggist, fatal error of, 31.
Druggists violating the law, 671.
Dundore, Claude A. — Wiring the fragments in simple fractures of the lower extremities, 327.
Duodenal ulcer; sudden enormous hemorrhage; death, 471.
Dysentery, salol in, 125.
Dyslexia, case, 518.
Dysmenorrhœa and other pelvic pains, galvanism in, 559.
Dyspepsia, nervous, 413.
Dyspnœa, strophanthus for, 753.

Ear, middle, catarrh of, 642.
Eczema, of anus and genitalia, 255; therapeutics of, 410; of dentition, 557; of the nails, 690.
Editorials:
Abortion in Chicago, 88.
Abscesses, classification of, 247.
Accounts rendered quarterly, 53.
Alexander's operation, 119.
American Medical Association, meeting of the, 374; 767.
American Public Health Association and the New York Herald, 403.
Aortic regurgitation, capillary pulsation in, 608.
Arkansas State Medical Society, 522.
Arthrectomy at ankle joint, 214.
Bishop, Mr., autopsy on, 663.
Bladder, an artificial, 147.
Bladder, extirpation of tumors of the, 279.
Bowels, secondary occlusion of, following laparotomy, 607.
Calomel injections, danger of, 181.
Camphorated naphthol, 280.
Cancer of cervix uteri, early diagnosis of, 462.
Cancer, treatment by electricity, 748.
Capillary pulsation in aortic regurgitation, 608.
Carcinoma after operation, prognosis of, 52.
Chicago Insane Asylum, 665.
Chloroform, preservation of, 374.
Cocaine-habit, death caused by, 280.
Cocaine injections into urethra and bladder, dangers of, 520.
Coccyx in labor, function of the, 436.
Cornea, infectious ulcers of, 247.
County society sustained in court, 640.
Death, hour of, 720.
Dental fistulæ, 492.
Diphtheria, treatment of, 118; 401.
Doctor's badge, 184.
Editor and advertiser, relation of, 403.
Electricity, execution by, 55.
Ending, an abrupt, 184.
Endometritis puerperal, treatment, 719.
Epilepsy, essential, pathological anatomy, 749.
Episcopal Hospital, generous gift to, 554.
Fluorine as a remedial agent, 53; 748.
Foreign bodies in alimentary canal, expulsion of, 280.
Foreign bodies, removal of, from the nose, 248.
Four years' course, 519.
Gall-bladder, excision of, 463.
Growth of bone, artificial stimulation of, 212.
Head-downward presentation, 371.
Heart disease, prognosis of, 691.
Hernia inguino-superficialis, 554.
Homœopathic physicians, obligations, 553.
Hospital for the insane, a reporter in, 610.
Hospital treatment, 373.
Hydrophobia, judicious management of a case of supposed, 87; result of Pasteur's treatment, 721.
Hymen as an evidence of virginity, 664.
Hysteria in children, 437.
Hystero-epilepsy in a man, 637.
Hysterorrhaphy, 213.
Idleness and insanity, 749.
Insane, state asylums or alms-houses for, 149.
Insanity, idleness and, 749.
Iodoform and cadaverin, 214.
Japan, advance of medicine in, 581.
Jefferson Medical College, chair of surgery at, 611.
Johnstown, Pa., disaster at, 691.
Kidneys, palpation of the, 435.
Labor in women with flat pelves, 493.
Lectures, published without permission of the author, 281.
Leidy, Dr., a tribute to, 26.
Locomotor ataxia, treatment of, by suspension, 246, 464.
Mackenzie, Morell, again, 464.
Medical Examiners' Bill in Pennsylvania, 344.
Medical Examiners, State Board of, 117, 245, 491.
Medical journals, consolidation, 749.
Medical witness, deception of, 211.
Michigan State Medical Society, 522.
Milk and the public health, 638.

Milk, regulating sale of, 183.
Murder by an insane man, 641.
New Hampshire State Medical Society, 693.
New Jersey, Medical Society of, 666.
Not cruelty, but not sport, 27.
Ohio State Medical Society, 583.
Ozæna, treatment with glycerine, 403.
Pennsylvania State Medical College, 611.
Pennsylvania State Medical Society, 693.
Pennsylvania, University of, election at, 184.
Philadelphia County Medical Society, 281.
Philadelphia Hospital, 148.
Philadelphia Hospital and the Mayor, 579.
Philadelphia Hospital, the charge against, 637.
Philadelphia Polyclinic, 214.
Phthisis as a neurosis, 120.
Phthisis, infectiousness of, 343.
Physician, imposing on a, 281.
Physicians, an accusation against, 25.
Physicians and prohibition, 461.
Physicians, protection for American, 88.
Physiology, women teachers of, to girls, 693.
Picrotoxin as an antidote to morphia, 402.
Post-partum hemorrhage, tamponing for, 494.
Pregnancy, diagnosis of by external examination, 341.
Presbyterian Hospital, 215.
Prohibition, physicians and, 461.
Prostate, enlarged, treatment of, 343.
Publishing lectures without permission of the author, 281.
Puerperal endometritis, treatment, 719.
Puerperal sepsis, treatment, 182.
Pylorus, operation for stenosis of the, 54.
Railway spine, 768.
Readers, confidential word to our, 147.
Rectum, resection of, 521.
Ringworm, chronic, new treatment for, 747.
Sacro-coccygeal route for intrapelvic operations, 580.
Small-pox and vaccination at Sheffield, 664.
Small-pox, suppression of, 553.
Sparteine, sulphate of, 609.
Spine, the railway, 768.
Stupidity, British, 184.
Tetanus neonatorum, 182.
Times, the, and the *Register*, 583.
Tonsillitis, treatment of, 248.
Trephining, replacing the bone after, 665.
University of Pennsylvania, election of professors at, 89.
Vaccination and small-pox at Sheffield, 664.
Vetinary medicine, regulating, 51.
Virginity, hymen as an evidence of, 664.
Weil's disease, or infectious jaundice, 551.
Williamson, Isaiah V., bequests of to medical charities, 373.
Wisconsin State Medical Society, 611.
Yellow fever conference in Florida, 492.
Yellow fever panic, 26.
Edwards, C. P.—Lycopodium dressing for ulcers and wounds, 424.
Electricity, its physics and therapeutics, 428–430; for executions, 159; execution by, 752.
Electric light, influence of, on eyesight, 310.
Electrolysis, for alterations in prostate caused by gonorrhœa, 92.
Elephantiasis, congenital, 689.
Eliot, Llewellyn.—Stomatitis gangrenosa, 225.
Encephalocele, case of, 76.
Endometritis, treatment of puerperal by the curette, 45; gravidarum polyposa, 109.
Epilepsy, Jacksonian, 395; trephining in, 657; and aneurism, Dr. Macewen on, 667; simulo as a remedy in, 726.
Epithelioma, 238.
Ergot, action of, on uterus, 210; hypodermically, in facial neuralgia, 285.
Erysipelas, of pharynx and face, 172; remedy for, 222; contagiousness, 512.
Eschscholtzia Californica: a new hypnotic, 286.
Ether, death under, 653.
Etherization, abuses in, 753.
Etiquette, question of, 217.
Euphorbia pilulifera in asthma, 319; 612.
Eustis, W. C.—The conjugal question, 10.
Excision, arthrectomy a substitute for, 510.
Exostoses, multiple, 393, 574.
Expectorant mixture in use at Bellevue Hospital, 636.
Experience, perilous, of a doctor, 158.
Eye-ball, dislocation of, 142.
Eye-lids, syphilitic disease of, treatment, 222.

Facial paralysis of the new-born, 234.
Febriline, a so-called "tasteless quinine," 586.
Fecal fistula, 714.
Felon, case of, 238.
Fever, typhoid, 40; yellow, 55; typhoid in West Virginia, 58; accidental rashes in typhoid, 62; experimental researches upon etiology of yellow, 110; typhoid, beta-naphthol in, 138; typhoid, its care and treatment, 152; treatment of typhoid, 208; scarlet, incubation of, 252; eruptive, influence upon syphilis, 498.
Fielde, Adele M.—Color-sense and color-blindness among the Chinese, 651.
Fingers, congenital absence, 723.
Fissure of anus and spasmodic urethral stricture, 241.
Fistula, entero-vesical, Senn's hydrogen gas test for diagnosis of, 77; fecal, 714.
Flat-foot: new plantar spring for its relief, 416.
Flick, Lawrence.—Infectiousness of tuberculosis, 678.
Fœtal blood at birth, 116.
Fœtal cardiac rhythm, significance, 743.
Fœtation, extra-uterine, 13.
Fœtus, unique presentation, 550.
Food adulteration, prevention of, 126; defeat of bill for, 379.
Food for shipwrecked seamen, 255.
Foods for the sick, 33.
Forbes, William S.—Some new instruments, 760.
Forceps, danger of, 335; obstetric, remarks on use of, 535, 544.
Foreign bodies, removal of hook-shaped, 115; (*see* intestines, button-hook in).
Fractures, of the extremities, immediate treatment, 103; treatment by wiring, 327; of skull, compound, 376; of clavicle, 393.
Friedreich's disease, 276.
Furunculus of the ear, 606.

Gallant act, 223.
Gall-bladder, statistics of operations on, 190; surgery of, 689.
Galvanism in dysmenorrhœa and other pelvic pains, 559.
Gangrene, symmetrical, 488; 687; traumatic, of finger, 548.
Garbage, disposal of, 284.
Gargle for inflammatory throat troubles, 636.
Gas-cysts of the vagina, 276.

Gastrostomy, successful, 60.
Genu-varum, double, 683.
German students and their habits, 82.
Gland, caseous in the trachea, death from, 145.
Gleason, E. Baldwin. — Treatment of catarrhal diseases of the nose and throat at the Union Dispensary, 321; subcutaneous use of mercury in syphilitic affections, 645.
Glycerine, effects of on vaginal secretions, 91.
Goitre, extirpation of, 654.
Gonorrhœa, electrolysis for alterations in prostate caused by, 92; treatment, 431; clinical observations on, 558; abortive treatment of, after cocaine anæsthesia, 754.
Gonorrhœal diseases of the uterine appendages, 328.
Gonorrhœal infection, compound, 278.
Gonorrhœal orchitis, anemone pulsatilla in, 285.
Gonorrhœal rheumatism, 505, 540.
Goodell, William.—Cæsarean section for carcinoma of the cervix uteri; the new Sänger operation, 381.
Good form in doctor's cards, 151, 284.
Gould, G. M.—Three remarkable cases of reflex neuroses due to eye-strain, 164; influence of sexualism in reflex ocular neuroses, 302.
Graham, James.—Western North Carolina as a health resort, 648.
"Grass-bur" in left bronchus, 91.
Green, Traill.—Treatment of tapeworm, 424.
Gun-powder, heroic method of removing, 152; removal of from the face, 249, 284.
Gynecological operations, acute mania, etc., following, 482.

Hæmatoxylin, alcoholic solution of, 254.
Hæmaturia, treatment, 614.
Hæmoglobin, formation in the spleen, 396.
Hair, regeneration of, 218.
Hairs, superfluous, 217.
Hammer palsy, 395.
Hands, how to preserve, 434.
Happel, T. J.—Tubercular meningitis, 71.
Hardcastle, Jerome.—Value of chloral hydrate, 737.
Hare, H. A.—Fatality of cardiac injuries, 729.
Hare-lip and cleft-palate, 710.
Harvey, Thomas W.—Acetized cotton, 266.
Haverford College, appointment at, 349.
Headache in inebriety, 357.
Heart, diseases of: hill-climbing for, 116; slight aortic insufficiency, 243; Prof. Sée on, 399; cardiac hypertrophy, dilatation, etc., 456; fatality of cardiac injuries, 729; valvular incompetency due to blood state, 758.
Heart failure, influence of stomach digestion in its production, 381.
Hegar's sign of pregnancy, 713.
Helm, E. C.—Immediate treatment of fractures of the extremities, 103.
Hemorrhage, from the mouth, death of an infant from, 430; intra-cranial, 430.
Hengst, D. A.—Case of encephalocele, 76.
Henry, F. P.—Scurvy, 446; scurvy in a hemiplegic. Pulmonary phthisis, 501.
Hernia, a few points in Macewen's operation for, 112; inguinal, treatment with reference to radical cure, 305; diaphragmatic, reduction, 630.
Herniotomy, result of, 217.
Hip-joint disease, 335; immediate correction of deformities from, 398.
Hoarseness, immediate relief of, 725.
Hodges, F. J.—Valvular incompetency, 758.
Holmes, Dr., and his books, 497.
Homœopath, what a patient may demand of, 556.
Homœopathy, defense of, 186.
Hot air, inhalation of, in phthisis, 635.
Howard Hospital, 699.
Huber, L.—Climatic treatment of pulmonary consumption, 227.
Humbuggery, pseudo-scientific, 156.
Humerus, sub-spinous luxation of, 77, 266.
Hunt memorial hospital, 159.
Hydracetin, the new antipyretic and analgesic, 764.
Hydrophobia, 605.
Hyperidrosis among soldiers, 525.
Hypnotism, interesting demonstration of, 203; vile abuses of, 204.
Hysteria in infants, 558.
Hysterectomy for large fibromyoma, 681.
Hystero-epilepsy, cure by extirpation of uterine appendages, 629.

Ichthyol, 698.
Ichthyosis, treatment of, 283.
Idiocy, is instrumental delivery a cause of? 158.
Illuminating internal organs, new method of, 189.
Impotence consequent on varicocele, 576.
Indian doctor, native, 440.
Inebriate asylums, 347.
Inebriety, headache in, 357; damages for death from, 585.
Infanticide in China, 155.
Infants, method of conducting post-mortem examinations upon, 391.
Infection, is the communication of an assault, 30.
Ink, blue-black writing, 499.
Insane, care of, in Pennsylvania, 153; crowded hospitals for, 386; specialists for asylums for, 614.
Insanity, acute chorea and, 139; and sex, 496.
Insomnia, treatment of, 275.
Instruments, some new, 760.
Intestinal obstruction, caused by linseed, 92; when to interfere in, 487.
Intestines, button-hook in, 206.
Intubation, recent observations relating to, 146; with an ordinary rubber tube, 242; in diphtheritic croup, 516.
Iodide of potash, purpura from, 222.
Iodoform in tubercular diarrhœa, 139.
Iodol, therapeutics of, 189; in diseases of the respiratory organs, 716.

Jaborandi, 42.
Jackson, Edward.—Failure of vision in old age, 257.
Jaundice, in the new-born, 235; pilocarpine in itching of, 586; and ophthalmia neonatorum, 658.
Jefferson Medical College, commencement, 469.
Johnson, J. B.—Formula for croup, 174; the conjugal state, 230; sedative and laxative mixture, 512.
Johnstown, disaster at, 696; news and notes from, 723–725; sanitary condition, 770.

Keen, Dr. W. W., and the Woman's Medical College, 643.
Kemper, G. W. H.—Antiseptics in normal labor, 734.
Knee-joint, exsection, 688.
Knock-knee, 547.

Labor, induction of premature in contraction of the pelvic inlet, 431; in occipito-posterior positions, 669; normal, antiseptics in, 734.
Lactic acid in chronic suppurative otitis media, 207.
Lanolin, in suppositories, 251; and mercury in affections of the cornea, 670.
Laparotomy, for injury by circular saw, 20; for probable tumor of uterus, 22; for tubercular peritonitis, 447; for intrapelvic injury, 479; use of corrosive sublimate in, 629.
Larynx, foreign body in the, 83; frequency of cancer of, 116; thyrotomy for malignant disease of, 180; extirpation for cancer, 687.
Laxative suppository, the ideal, 203.
Lead palsy, 202.
Lead poisoning, influence on pregnant women, 527.
"Lemonade iron," formula for, 698.
Leprosy, inoculation with, 84; inoculability of, 127; transmission of, 219; 309; Dr. Morrow's observations on, in Mexico and the Sandwich Islands, 762; danger of spread of, in the United States, 763.
Leuf, A. H. P.—Some obstetric cases, 5.
Levis, Dr., proposed tribute to, 699.
Leyden, Prof., 659.
Lipomata, case of general, 238.
Liver, cirrhosis of, in cats, 223; cirrhosis, 252; resection of, 656; elastic suture of, 658.
Locomotor ataxia, and general paralysis, 469; treated by extension, 684; danger of the suspension treatment, 726.
Long, J. A.—Typhoid fever, 40.
Long, J. W.—Practical Aseptic Surgery, 261, 299.
Lung affections in children, creasote in, 585.
Lupus erythematosus, treatment of, 201.
Luxation of humerus, sub-spinous, 77, 266.
Lycopodium dressing for ulcers and wounds, 424.
Lyman, H. M.—Syphilis complicated with epileptiform convulsions, keratitis, etc., 129.

Malarial fever, hemorrhagic, 668.
Malignant disease, relation of purpura to, 368.
Mania, acute, and melancholia, or hypochondriasis, as sequelæ to gynecological operations, 482.
Manikin, obstetrical, 108.
Massage in pelvic inflammation, 409; electric, 662.
Mastitis after death of the infant, 484.
Maxwell, G. T.—Ablation of tonsils when smaller than natural, 196.
McCoy and Wildman, case of Drs., 121.
McGuire, C. F.—Physical education, 705.
Measles and diphtheria, mode of transmission, 517.
Medical candidates in Germany, 205.

Medical Examiners' Bill and the Medico-Chirurgical College, 349.
Medical Examining Board, 249, 496.
Medical Missions in the East, 157.
Medical practice act, Governor of Illinois on, 441.
Medical practice in Michigan, 411.
Medical profession, important notice to, 751.
Medical students, American, in Vienna, 125.
Medical students, threatened revolt of, 94.
Medical witnesses, are they to be subjected to new tests? 283; treatment of, 439.
Medicine, methods of instruction, 524; license to practise, 603; method of giving it to children, 614.
Meningitis, tubercular, 71.
Meningocele; ligation of and removal of sac, 85; a case of, 265, 346.
Menstruation and chlorosis, relation, 549.
Mercury (*see also* "corrosive sublimate"), poisoning with cyanide of, 82; biniodide of, its antiseptic use, 267; poisoning with sulphocyanide, 400; oxy-chloride, an antiseptic, 526; -lanolin in affections of cornea, 670; biniodide of, cotton impregnated with, 727; bichloride of, in anæmia, 754.
Michigan State Medical Society, 529.
Microörganisms, voluntary coöperation of, 669.
Midwives in West Virginia, 723.
Middleton Goldsmith lecture, 184.
Milk, regulation of sale of in Philadelphia, 188; skimmed, plea for, 250; nature of, 255; secretion, following ovariotomy, 326; new and simple method of estimating per cent. of fat in, 408; bacteria in, 408; adulterated, 527.
Milner, J. C.—Strange effect of nervous shock, 231.
Minich, J. A.—Removal of two-thirds of a rib, 229.
Minnesota Medical act, 287.
Missile, odd course of a, 44.
Missions, Medical, in the East, 157.
Monkeys and parasites, 378.
Monoplegia, hysterical in a man, 636.
Mouth, absorption of tissues of the, from pressure, 278.
Mucilaginous ointment, formula for, 770.
Mumps in an aged person, 600; and double orchitis, 712.
Muscular atrophy, progressive, 366.
Musgrove, Charles W.—Mumps in an aged person, 600.
Mushrooms, toxic action of edible, 460.
Musser, J. H.—Tuberculosis, 97.
Myrthol, disinfection of air-passages with, 63.
Myxœdema, an affection allied to, 392; case, 688.

Nails, eczema of, 690.
Naphthalin in typhoid fever, 219; rash from, 242.
Naphthol, beta, in typhoid fever, 138; as a local antiseptic, formulæ for, 670.
Nasal bougies, 146 (*for correction see p.* 187).
Nasal obstruction, removal of, results in 112 cases, 79.
Nasal passages, obstruction of; its effects and treatment, 589.
Nasal polypi, removal during hypnotism, 126.
National Association of Railway Surgeons, 411.
Naval Board of Medical Examiners, 191.
Necrosis, of great toe and its metatarsal bone, removal, 575; of tibia, 635; of lower jaw, 683.
Nephrectomy for floating kidney, 397.
Nephritis, treatment of acute and subacute, 361; subacute diffuse, 458.
Nervous anæmic women, formula for use in, 699.
Nervous disorders, functional, sedative and laxative mixture for, 512.
Nervous shock, strange effect of, 231.
Nervous system, central, surgery of, 603.
Neuralgia, facial, hypodermic injections of ergot in, 285; treatment by extraction of nerves, 687.
Neurosis traumatic, 687.
New Jersey State Medical Society, 769.
New York Academy of Medicine, 63.
New York Maternity Hospital, fight at, 440.
Neuritis, peripheral, 62.
Neuroses, cases of reflex, due to eye-strain, 164.
Nipple and its areola in pregnant women, 235; operation for depressed, 715.
Nitroglycerine, suggestion of a new use for, 138.

Noble, Charles P.—Senn's hydrogen gas test for diagnosis in cases of entero-vesical fistula, 77; technique of abdominal palpation, 168; remarks on the use of the obstetric forceps, 535.
North Carolina, western, as a health resort, 648.
Nose, treatment of diseases of, by the general practitioner, 45; frequency of diseases of, 190; catarrhal diseases, treatment, 321; obstruction of, recent advances in treatment, 718; large gumma in, 766.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

"NORTH CAPE"
Norwegian COD LIVER OIL.

IN STONE BOTTLES, Pints and Quarts.

This Oil is very carefully made from the finest fresh livers, and from the time of its production is kept totally excluded from LIGHT—a course that has been proved necessary to retain the entire medicinal value of the Oil.

On this account it will be found infinitely superior in palatability and digestibility, and in all cases where its use is indicated, positive benefit quickly follows its administration.

COD LIVER OIL DETERIORATES RAPIDLY WHEN EXPOSED TO LIGHT.
THE "NORTH CAPE" IS CAREFULLY PROTECTED FROM LIGHT, AND WILL REMAIN FRESH AND SWEET INDEFINITELY.

To avoid confusion and to insure satisfaction, be particular to specify "NORTH CAPE" Cod Liver Oil.

Imported by JOHN C. BAKER & CO., 815 Filbert Street,
PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

FIBRO-CYSTIC TUMOR OF THE UTERUS; UNUSUAL TREATMENT; CURE.[1]

BY E. J. BEALL, M.D.,
FORT WORTH, TEXAS.

At the April, 1887, meeting of the Texas State Medical Association, I presented a paper upon uterine fibro-myomata complicating delivery. In that paper I strongly urged enucleation in lieu of other measures, and gave the history of a case in which I enucleated a fibroid weighing three pounds, that completely blocked the pelvis, having incarcerated behind it a male child weighing fully ten pounds. The case was successful in every particular—mother and child both well at the present time.

Twelve weeks ago I was called in consultation with one of the most intelligent physicians of this section to see Mrs. S., aged 37 years; married one year; had never conceived. Her mother, a sister, and a maternal aunt died of "malignant disease" within the abdominal cavity. Upon her cousin I had performed laparotomy for intra-peritoneal abscess that followed childbirth. She had suffered from metrorrhagia for several years. Some time prior to marriage her abdomen had begun to enlarge, and at the time of my visit the fundus uteri reached a point somewhat above

[1] Read at the meeting of the Southern Surgical and Gynecological Association, Birmingham, Ala., Dec. 7, 1888.

the umbilicus. She was anæmic from profuse and protracted hemorrhage, and had more or less abdominal pain.

A few days before I visited the case, an electrical trocar had been introduced into a fibro-cystic tumor that extended into and very much distended the vagina. As a result an ulcerative gangrenous process had arisen, attended with slight flow and odor. To the above procedure, though strict antisepsis had been observed, I attributed the elevated temperature and increased frequency of pulse I found present at my visit. Yet, some days prior to the elevation of temperature there had existed fever, which readily responded to quinine, and the patient lived in a malarious locality. The abdomen presented a symmetrical contour; the enlarged and elevated uterus inclined only slightly toward the right side.

An examination disclosed a hard, slightly elastic tumor, filling a very much dilated and elongated vagina, extending to and slightly bulging the labia and just within a firmly closed and rigid ostium. The finger could be swept around the mass; the edges of the cervix uteri could be made out, but it was widely dilated and occupied by the growth.

As the tumor gradually developed, the uterus was both dilated and elevated, and the vagina dilated and lengthened. A sound could be introduced into the uterus on one side to a considerable depth; but the sound movement was quite limited, and indicated a very lengthened and narrow cavity unoccupied by the attachments of the growth. This led me to infer that I had a tumor to deal with, the attachments of which, to the internal surface of the uterus, were quite extensive. Palpation and percussion also indicated a large, firm, very slightly elastic tumor, doubtless fibro-cystic, filling the vagina and elevating and enlarging the uterus to the dimensions already indicated.

These facts of the case well in mind, what course should be pursued which would prove safest for a patient whose life is in the balance, to be turned for weal or woe by the act needed to be carried out by the physician for relief?

It may be well to review some of the measures hitherto suggested for the treatment of uterine fibroids that the hearer may be prepared for comparison when I present the plan adopted, and which terminated so happily in this case.

Palliative treatment, while applicable to minor and less severe cases, promised little in the one under consideration. Correcting displacement of the uterus was not indicated. Arresting hemorrhage by hæmostatics, tampon, rest, etc., could only put off the inevitable day for action of a decisive character. The medical treatment by alterative agents, whose office, it is thought, is to induce fatty degeneration; the use of ergot, which in some cases has produced good results, when tumors were decidedly interstitial or perhaps subserous, more particularly the former, when muscular contractility (the result of ergotism) would induce compression by muscular fibre—this method was not, to my mind applicable; at least it would be fraught with danger, by reason of the delay needed before radical results could be expected.

From reading and experience I could not expect that electrolysis, so strongly urged by Apostoli, could effect changes in the growth with sufficient rapidity and thoroughness, nor sufficiently exempt from danger, to commend it to this case, which I thoroughly believed, required prompt, immediate measures.

To the art of surgery and its ready application I now turned for a remedy.

1st. Was abdominal section advisable? I believe there are those who would have resorted to the measure. That road has many a warning post, to one of limited experience, at every crook and fork; like a boatman slowly and gently descending some placid winding stream; suddenly and unexpectedly he encounters unforeseen rocks or falls, while just before, everything was merrily well. The abdomen opened, an enlarged uterus and fibro-cystic contents turned over the pubes; the broad ligaments ligated off; a large dilated and filled cervix to be cobble-stitched around, secured and tied, disengaging a mass from its circular grasp; that cervix as large as the calf of one's leg—all this is pretty to read about in books and journals; it is exciting, and does well when one has the ægis of a metropolitan hospital, with its reports fingered only by the actor, and has leisure for study of results at a dead-house, the janitor his vigil; but not upon the living woman, at a farm-house; the laity his audience; the husband, the mother, the sister hard by the operating-table, urging the surgeon to seek a safer, less formidable plan of treatment, if his conscience will allow and his judgment devise such.

2d. As the tumor could be drawn downward, should I attempt to cut it away with scissors? This is sometimes practicable, and has been done often.

3d. After traction with volsellum, should

I endeavor to encircle the mass with the écraseur and sever it as near as practicable to its fibrous attachments?

4th. Should I endeavor to remove the tumor with Dr. Thomas's serrated spoon, as has been done rapidly, safely, and surely, so often, by that brilliant man and his followers?

5th. Should I enucleate, as I had done in former cases—a notable instance of which I have heretofore brought before the profession?

The high opinion I entertain of this last measure induced me to preface this paper with a reference to a case in which I put that plan into successful execution. It is, in many instances, easily done, and attended with little danger. I urge the method when practicable, which it is in very many interstitial, submucous, and mixed tumors. My first effort in this case was to institute the enucleation process. At several places I essayed the plan, but signally failed: the capsule could not be peeled from the growth.

To have incised the capsule and endeavored to force a gradual extrusion of the intracapsular fibro-cystic growth by ergot, would have involved much time, besides subjecting the patient to further systemic infection.

To the first proposition: Disinclination, by reason of inexperience, and fear of shock, etc., prevented its adoption.

To the second and third: I could not consent for various reasons: pertinently, portions of the mass would have been left, presenting a surface through which poisons could readily reach the uterine sinuses and lymphatics, and thus originate a process of systemic infection fraught with great danger.

To the fourth: The objections urged against the second and third are of equal import here. Additionally, in the hands of one whose experience with the Thomas serrated spoon is limited, uterine tissue might be injured—even the peritoneal cavity might be invaded.

Having referred to the more prominent measures relied upon for the removal of growths connected with the uterus, it must not be inferred that cases do not occur to which these various plans are applicable. But to tumors with a broad and extensive intra-uterine attachment, the sawing process, the *écrasement*, or the incision must be followed by a digging-out of tumor remains: a harsh usage of the uterus, accompanied by the danger that belongs to shock, hemorrhage, etc. Even after much digging, tumor elements will be left which may develop again at a future time, entailing perhaps, if nothing more, a hemorrhagic condition of a new endometrium, great risk of infection, etc.

I do not claim that the manner in which I treated the case, the technique of which I am about to relate, is without precedent. But the plan has no advocates; and if such cases are known to others of the profession they may have had similar management accidentally, not intentionally. This, however, is not so in my own case. What I did was not an accident growing out of an effort to do otherwise; but was the outcome of premeditation.

If I am to be criticized for the method pursued it must not be ascribed to rashness, but to sober thought and conscientious conclusions. At all events, the patient lives; the interested ones are of a good family and happy; and I have the knowledge that they have applauded and appreciated the services rendered in this most interesting case.

The patient was placed in the dorsal position, the hips elevated, and chloroform administered. Sawyer's forceps were introduced as high as the cervix and caused to embrace the tumor; gentle traction with slight to and fro movement was exercised. Very soon the labia and perineum were being bulged outward by the tumor upon which traction was being made. The left hand was held upon the enlarged abdomen, and the uterus could be felt descending *pari passu* with the advance of the tumor within the grasp of the forceps. At this stage of the operation I intended doing an episiotomy to avoid an irregular laceration of the perineum, which was becoming pronouncedly distended. I did not do so, however, but elevated the handle of the forceps and endeavored to keep apace with the perineal tension. By external palpation and intra-vaginal examination I watched the lowering of the uterus and condition of parts as delivery progressed. Just here, notwithstanding the traction was cautiously and gently done, I discovered that the thinned perineum was giving away. I had now withdrawn at least a pound of the seven-pound growth beyond the external genitalia, and at once instituted search for cysts, upon finding which I opened and relieved of viscid colloidal material, thus reducing the mass I was endeavoring to remove. I then enlarged the perineum; made further traction, and further reduction by disposing of other small cysts. Pursuing this plan I was soon enabled to introduce my hand (having removed the forceps) by the

side of the tumor, grasp it and make more intelligent traction. A few minutes later I could insinuate my hand into the uterus, grasp the tumor more firmly, and determine that the attachments were very general. Instead of removing large portions of the tumor and allowing fragments to remain, I determined gently to *invert the uterus*, which I did, and bring in view the attachments of the growth, in order more thoroughly to separate it from the uterine wall, and better stanch the bleeding with hæmostatic forceps and hot sublimate water. The tumor now being entirely removed by aseptic fingers and scissors; a hypodermic of ergot having been given; the bleeding all stopped, I *returned the uterus* to its normal position with great ease. The perineum was neatly stitched with number three gut ligature, and patient put to bed, knees tied together.

Doing what I did, I could observe strict antisepsis. I left nothing within the uterus, nor returned anything for septic mischief. Little or no shock supervened, and but little hemorrhage. The patient was soon comfortable. No fever or other untoward circumstance retarded a rapid restoration to health.

The perineum was primarily united; menstruation is occurring normally; health is re-established; and a happy husband has a happy housewife, in every way qualified for her duties, domestic and marital.

TRAUMATIC TETANUS.

BY WILLIAM C. TODD, M.D.,
ROXBOROUGH, PA.

I have just treated a case of traumatic tetanus, which terminated in recovery, and it occurred to me that a short account of some cases which have happened recently in my practice may be of interest.

Case I.—J. B., a lad 13 years old, in running barefoot along some rough boards, had a splinter about three inches long enter the foot under the toes, and penetrate deeply into the centre of the foot. Nothing was done for several days, until symptoms became serious. When called in, I found tetanus fully developed; the jaws being locked and the whole body bent forcibly backward, with occasional spasms in which the tongue was bitten. The foot was much inflamed, swollen, and very painful. An anæsthetic was given, the part laid freely open, and the splinter removed; warm emollient poultices were then constantly applied, and the room was kept at a warm and even temperature. He was kept under the influence of full doses of chloral and bromide of potash, with belladonna applications along the spine. Liquid food was given at regular intervals, and special attention was given to the proper action of the bowels and kidneys. The result in this case was recovery in four weeks.

Case II.—M. P., a young man 15 years old, received an injury of the foot on the railroad, by which the great toe and metatarsal bone of one foot were partly crushed. In a few days tetanus set in. He was treated in much the same way as the patient just mentioned, and recovered in three weeks.

Case III.—A. H., a boy 13 years old, received a wound in the hand with a toy pistol. About a week afterward tetanus set in very violently. Various remedies were tried without any apparent benefit, death taking place on the third day.

Case IV.—W. T. A., 14 years old. In this case the great toe was crushed by being run over with a wagon-wheel. When recovery had nearly taken place he contracted a cold. The result was a chill followed by tetanus. Treatment in this case was the same as in the first case, with recovery in four weeks.

Case V.—R. B., a painter, 34 years old, had a fall from the second story of a house, and suffered a compound fracture of the forearm. On the fifth day after the injury tetanus set in. Treatment in this case was the same as in the first case at the beginning; but his temperature going up to 104° Fahr. a few doses of antipyrin were given, with the effect of reducing the temperature. Tincture of Calabar bean was given in gradually increased doses in this case, but without the slightest benefit, death taking place on the fourth day.

Case VI.—C. McA., a young man 16 years old. The thumb was crushed in a mortising machine. About a week afterward he was exposed to a cold, which was followed by an attack of tetanus. Treatment in this case was that already described, the result being recovery in four weeks.

In the cases that recovered there was very much prostration for some time afterward, and all the patients required tonics, nourishing diet, and careful nursing.

I am indebted to my friend Dr. W. W. Keen for valuable services, in consultation, in several of the above cases.

It will be observed that in six cases of traumatic tetanus, there were four recoveries and two deaths.

SOME OBSTETRIC CASES.

BY A. H. P. LEUF, M.D.,
OF THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

The following cases were put together after the reading of those reported by Dr. Charles P. Noble, in the REPORTER for August 25, 1888. My only object in publishing them is that they may prove instructive in a practical way to some of those readers whose gaze they may encounter. It is also supposed that some of them might gladden the heart of the ever-searching statistician. I have purposely omitted detailed accounts because they seldom have any value, but should anyone desire additional information, I promise gladly to forward it.

Case I.—Abortion; High Fever; Peritonitis; Rapid Digital Dilatation of Os and Removal of Putrid Placenta.—In the summer of 1882, I was called to see a young woman, who was the mistress of a medical student who has since died, and upon whom he had performed an abortion at the fourth month of gestation. He had at first called in another physician who gave the patient repeated small doses of ergot, opium, brandy, and chloral, with a little quinine; but these did her no good, and when I saw her on the fifth or sixth day, her temperature was 106° F.; she was delirious, the pulse was very rapid, the abdomen was much distended and extremely tender, there was a very fœtid vaginal discharge, the uterus felt soft, and the edge of a small placenta could be felt projecting from the os. I ordered a half-ounce of fluid extract of ergot, a half-drachm of hydrate of chloral, and asked that the attending physician meet me there in four hours. He was a graduate of only two months' standing, though a practitioner of many years. Upon my return, he was afraid to do anything, believing that the patient would die. The student began to give chloroform by dropping it from a bottle stoppered with a grooved cork. Instead of letting it fall on the towel over the patient's mouth and nose, he was so excited that he squirted it into her eye. I had to give it to her myself, and when fully under its influence, I rapidly dilated the os, seized the putrefying placenta with my index and middle fingers, and extracted it. The nozzle of a fountain syringe was passed up against the fundus and one quart of hot carbolic water allowed to pass through. The patient was then cleansed, put to rest, and given a hypodermic injection of gr. i of the sulphate of morphia, though the same amount had been given her a little over four hours previously in two doses to control excessive pain. In forty-five minutes I gave another half-grain, and after this she was relieved; the temperature fell rapidly and she was much improved in a few hours. Her improvement continued until the sixth day, when she insisted upon getting out of bed. The result was renewed peritonitis, but this was rapidly controlled by the prompt use of hot applications to the hypogastrium, and the injection of morphine.

Remarks.—The object in giving the ergot was to insure a tonic condition of the uterus and a diminution of its circulation before dilatation, and the chloral was given to insure a rest to the goaded nervous system before subjecting it to the additional strain of dilatation. The advisability of at once giving large doses of morphine for the arrest of the pain of peritonitis was well demonstrated in this case; smaller amounts would have been ineffectual and the pain would have caused additional weakness. The efficiency, expediency, and good effect of rapid digital dilatation in these cases cannot be questioned. The relief is prompt and immediate. I have had a number of such cases, and all have recovered promptly. I shall relate several more, and also a counter case. Unless a patient is already moribund, I see no reason why a case of abortion should die if rapid digital dilatation is resorted to as a means of relief. It seems to me that the thorough removal of the placenta in such cases is the most positive indication, and that it should be done without a moment's loss of time. It is a very prompt procedure, as it can almost always be completed without the additional use of an anæsthetic after the patient is once completely unconcious—at least, such has been my experience.

Case II.—Abortion; Rapid Digital Dilatation and Removal of Fœtus and Placenta.—In the summer of 1881, Mrs. X——, U. S., 18 years old, was a little over three months pregnant. She had pains in the back and a bloody discharge from the vagina. I gave her minimum doses of ergot and digitalis to control hemorrhage, and ordered the patient to bed; but her pains and hemorrhage became worse. On the second day she became feverish, and the pains had to be controlled with morphine. The membranes had ruptured, the os hardly admitted the index finger, and what appeared to be a foot occasionally presented

at the uterine orifice. I sent for assistance, gave chloroform, inserted my finger into the os, and dilated it with considerable difficulty, but in less than ten minutes, so as to be able readily to pass the index and middle fingers into the uterus, seize and thoroughly remove a dead fœtus and a quite firmly adherent putrescent placenta. The fever rapidly subsided and the patient made a perfect recovery in a little over one week.

Case III.—Abortion; Rapid Digital Dilatation; Removal of Uterine Contents.—In the fall of 1883, Dr. N. called me to see with him a case of abortion at three and a half months which had been self-induced by a young married woman, the mother of one child. He had attended her for several days and treated her with ergot, poultices, quinine and opium. She had considerable pain, due in part to peritonitis and in part to excessive uterine contractions. The vagina was hot and emitted the characteristic putrescent odor of these cases. The fetus had come away, but the placenta was still there and could plainly be felt. I also gave her an anæsthetic (ether in this case) and then turned it over to Dr. N., while I rapidly dilated the os, extracted the placenta which was in pieces, washed out the uterus with one quart of hot carbolic water, and made the patient clean and comfortable. Her recovery was prompt, rapid and uninterrupted. A hypodermic injection of morphine was given after the operation to insure freedom from pain and undisturbed sleep for several hours.

Case IV.—Abortion; Rapid Digital Dilatation; Removal of Fetus and Placenta; Chronic Myocarditis and the Harmless Use of Chloroform; Subsequent Death and Autopsy.—Mrs. H., U. S., mother of two children, thought herself pregnant and several times took the liberty of requesting of me an abortifacient, which was refused. She was a very good patient, a most devoted mother, having at the time of her last request just ended a two weeks' vigil over her small child, a girl of 3 years, during her suffering with, and recovery from, a double pneumonitis. I was called to see her at midnight, for the purpose of relieving her suffering in "miscarriage." I found her with a vigorously contracting uterus, a very small os, ruptured membranes, and a foot or hand presenting at the uterine mouth. She was a strong, well-built, and beautifully formed woman. The former physician, Dr. J., had told her that he feared she had some cardiac disease. I never had heard anything peculiar in listening to her heart, though she was very easily "winded." At all events I hazarded an anæsthetic, using chloroform myself with nitrite of amyl, and, instructing the husband how to keep it up, permitted him to continue it for a few moments while I rapidly dilated with my fingers and removed the dead fetus of 3 months and its placenta. I gave her a hypodermic injection of the fluid extract of ergot in the hypogastrium, and left her in good condition for the rest of the night. Her recovery was as prompt and satisfactory as that of any of the others, but on the fourth day she developed a dry pleuritis in the right infra-mammary region. This was treated with counter-irritation and small amounts of opium. She remained in bed. On the ninth or tenth day I left her in the evening almost well and anxious to sit up next day. I discontinued all medicine and promised her that she could consider herself my patient no longer after the next day. When I left her, her pulse was full, strong, and regular. At 5 A.M. the next day I was called to see her, and before I could leave I received a second summons. When I arrived she was dead. I sent for a student at my house and began artificial respiration and continued it with his aid till *post-mortem* lividity and slight rigor mortis began to set in, at the end of more than one hour. In addition to the artificial respiration, I tried cardipuncture but without any positive result. Then I tried a digitalis injection into the heart muscle or substance, but also without avail. She died just after awaking and asking for some medicine. When it was held to her mouth she refused it, saying that she would rest a moment before taking it, and she rested from that time on until I saw her dead. At the autopsy, I found a localized dry pleuritis at the diagnosed site over an area as large as the palm of the hand. The heart was pale, soft, fatty, and gave undoubted evidence of chronic interstitial myocarditis. The death was due to sudden heart failure; the heart was found filled with blood. The uterus showed a very slight remnant of red and softened endometrium, besides being somewhat enlarged.

Remarks.—The central point of interest in this case is the indifference with which the chloroform was borne, and the fortunate escape I had in not having my patient die during its administration. This case also certainly demonstrates that very serious disease of the heart does not absolutely contra indicate the use of chloroform, though I would prefer the safe side.

Case V.—Abortion; Retention of Placenta, and its Spontaneous Removal in 9 or 10 Weeks Without Bad Symptoms Except Menorrhagia.—In the summer of 1886, I attended Mrs. R., about 29 years old, U. S., and the mother of several children. She first came to my office to learn if she was pregnant, and I told her that she was. She did not want to go to full term, but failed in getting from me anything but the advice to let matters take their natural course. As is customary in most such instances, she tinkered with herself till she miscarried during the fourth month of gestation. She consulted me soon afterward for a menorrhagia which was due to the retention of all or part of the placenta. I gave fifteen minim doses of the fluid extract of ergot daily. This relieved the bleeding for a time, but it returned. The placenta was still in place. She objected to its removal, because it was still partly attached. Two or three hemorrhages followed, but they were not very copious. During the last one I was called to her and was still refused permission to remove the offending body. At last, about ten days later, she "flooded" quite freely and passed the cause of all the trouble, and soon recovered.

Remarks.—This case shows that retention of a placenta in a case of abortion is not necessarily dangerous, and that it may be carried for a long time, as in this instance, when it did not come away till nine or ten weeks after the loss of the fetus. Nevertheless, there is always some danger of more or less severe sudden hemorrhage in all cases in which it is retained and kept from putrefaction because of vascular union to the uterine wall.

Case VI.—Laceration of Vagina and Cervix during Labor; Peritonitis; Version; Death; Autopsy.—Mrs. O., 37 years old, married, Swede, mother of seven children, and about to be delivered of her eighth child. A midwife was in attendance during the present confinement and had been during the first three, but a regular physician had been employed for the last four. The patient had been in labor over twenty-four hours when Dr. R. was summoned. He found a transverse presentation with the child's left arm in the vagina and the head in the left iliac fossa (L. D. P.). The uterus was firmly contracted and the child apparently dead. The mother complained of intense pain in both iliac fossæ, but more especially on the left side. The midwife had been giving large doses of ergot at frequent intervals during almost the entire labor. Dr. M. was summoned to assist in the delivery. Podalic version was performed and a dead child extracted. Before anything could be done, the mother died of collapse.

Autopsy.—Feb. 27, 1883, I examined the body twenty-four hours after death. Body of average height, thin; yellow skin, light complexion. Both lungs were markedly congested, and the heart was flaccid, fatty and almost empty. The liver was fatty and the spleen soft and slightly enlarged. Both kidneys were fatty. There was marked injection of the vessels of the gastro-intestinal peritoneum, but without any disturbance of the mucous membrane. The uterus was well contracted, almost filled the pelvic cavity, and hardly projected above the true pelvic brim. There was a large laceration of the left side of the vagina from the utero-vaginal juncture almost to the vulva; its margins were widely separated. The portio vaginalis of the cervix was also lacerated as far as the junction. The margins of the tear were dark and sloughy. Considerable dark, grumous-looking malodorous fluid had passed into the abdominal cavity through this rent. Similar fluid had dissected its way up behind the peritoneum in the extra-peritoneal connective tissue of the left iliac and lumbar regions. The peritonitis was general; there was no lymph; and the vascular injection was most marked in the broad ligaments and both iliac fossæ, but especially in the left.

Remarks.—The large amount of ergot administered by the midwife had induced powerful tonic uterine contractions, which forced the child's head firmly against the left side of the cervix and vagina, compressing them between the head and pelvis for a long enough time to cause sloughing of the cervix and vagina of that side and eventual rupture. After this, it was easy for the liquor amnii remaining above the child and blood to find their way into the abdominal cavity and set up peritonitis. Thus the laceration and the strain of the continuous uterine contractions so exhausted the mother that, with her fatty heart, kidneys, and liver, she had a fatal collapse. She had been a moderate beer-drinker. The midwife was indicted by the coroner's jury, but the case never went to trial, so far as I can remember. This case shows the danger of using too much ergot.

Case VII.—Puerperal Peritonitis and Septicæmia Treated by a Midwife as "Afterpains."—Mrs. ——, married, German, multipara, was confined on the morning of

April 3, 1882. The next morning she had a pronounced chill, lasting fully one hour. There was also hypogastric pain, which increased in severity and became diffused over the whole abdomen. The patient was treated by the midwife for ordinary "after-pains." The pain being worse on the next day, a drug-store remedy was tried but gave no relief. Two bottles of citrate of magnesia were then taken and caused free evacuations. Dr. D. was called in two days later, the fifth since the labor. He found the patient in a state of extreme collapse. She was semi-conscious, and with a tongue so dry and swollen that her articulation was too indistinct to be understood. She also had subsultus tendinum. The pulse was 140, and the axillary temperature 105½° F. The abdomen was much distended, extremely tender, and tympanitic. There was persistent vomiting of dark gruelly matter. Death took place on the next day. There were, then, well-marked chills—the first on the second day after delivery, lasting fully one hour; the second on the morning of the fourth day, lasting one hour; and the third and last on the evening of the same day, lasting a half-hour.

Autopsy.—The examination of the body was made by me about fifty or sixty hours after death. The body was 5 ft. 6 in. long, emaciated, and of dark complexion. Markedly distended veins were visible all over the abdomen as high as the ensiform cartilage and around both thighs as far down as the knees. There was an extra-vulvar prolapse of the posterior vaginal wall (a rectocele), and slight reddening and vascular injection of the peritoneum of the hypogastrium. The gastro-intestinal tract appeared normal. The liver and kidneys were exceedingly soft, flabby, and pale. Both kidneys were so soft that they could be pressed longitudinally so that the finger-tips were but one inch apart. Both were granular. The bladder was 1½ inches above the pubic symphisis. The uterus extended half-way up to the umbilicus and was very relaxed and flabby.

Remarks.—This case serves to show how expensive it may be to employ midwives. A little care on the part of a competent obstetrician, or an early diagnosis, would probably have saved life.

Case VIII.—Post-Partum Hemorrhage Controlled by Prolonged Manual Pressure.—Mrs. D., 24 years old, a tall, stout and healthy multipara, was in her fourth labor in May, 1882. I was in attendance; the position was L. O. A.; the labor was normal, except the third stage. A severe and continuous hemorrhage set in soon after the delivery of the child and placenta, and all efforts to arrest it were unavailing. I tried hypodermic injections of ergot, amounting in all to one and one-half fluid drachms, in the hypogastrium; intra-uterine digital irritation (scratching); lemon-juice, vinegar, hot and cold water injections and external applications, and the external and internal use of ice. A clot as large as a fist had formed in the uterus, and still there was some oozing. Much to my immediate sorrow, I turned out this clot, not being satisfied to leave well enough alone. Thereupon the bleeding became more profuse than ever. My patient's surface was exceedingly pale, and she was cold even inside the vulva, in the axilla, and at the lips. The pallor of the lips was so marked that it was difficult to distinguish clearly between the mucous membrane and the integument. The uterus could not be identified by palpation, and per vaginam the cervix felt like a large, soft, flaccid, ragged rim. I pressed my flat open hand against the belly just below the umbilicus, and against the sacral promontory and pelvic outlet. The other hand was in the vagina, and could feel the blood slowly but steadily trickling from the mouth of the uterus. The patient by this time was unconscious and taking deep breaths, and sighing at intervals. Her head was lowered and her feet elevated, while rubber bags filled with hot water were applied to her lower extremities. No cardiac stimulant was given for fear that it would increase the hemorrhage. At last, after more than one hour's continuous manual compression, the bleeding ceased and the uterus could be felt as a large soft mass. It again contained a clot as large as a fist, and this I gladly permitted to remain. While making manual pressure, I occasionally stopped to see if it was any longer necessary, but only for an instant, for any slight relaxation would increase the flow of blood decidedly. My arms, especially the right, were weak and tremulous for days afterward from the continuous severe exertion, so as seriously to interfere with writing. Well-marked after-pains developed because, as I supposed, of the intra-uterine clot. Much to my surprise at that time, injections of hot water into the cervix, and for aught I know into the body, of the uterus caused an entire cessation of the pains at once and for four or five hours. The patient rapidly recovered without a bad symptom.

Remarks.—This case shows how difficult it sometimes is to account for, prevent, or control a post-partum hemorrhage, besides demonstrating the value of manual pressure when other means fail. Brandy or other cardiac stimulants were not given while the bleeding continued, and the fainting of the patient was looked upon with no little relief, as it was hoped that the weakened heart would be unable to force out much more blood from the open vessels, and so it happened. Again, this case teaches the value of hot water injections for the relief of after-pains. I have often had the same results since that time in preventing the same pains in my own cases and in those of others with whom I happened to be associated in the treatment of a case. I have also met with the same result in treating the pains of leucorrhœa and the vaginal catarrh itself by simple hot water injections, three or four times a day, each of at least 20 minutes' duration.

Case IX.—Contracted Pelvis; Post-partum Hemorrhage; Hour-Glass Contraction; Laceration of Cervix and Vagina; Retention of Urine; Recovery.—Mrs. H., about 24 years of age, married, German, stout and healthy, had had one miscarriage. Her uterine contractions were strong, the position of the child was L. O. A. She had a contracted pelvis and the child was full size. I called in Dr. H., at that time a hospital interne. Chloroform was given (chloroform f℥i and nitrite of amyl gtt. ii), and the forceps applied. It seemed almost impossible to effect delivery. The forceps were handed to Dr. H. for trial as he had never used any. Too much traction was made, and I renewed work with them. At no time did I pull with a force of more than about from ten to twelve pounds. The child was born in half an hour, but did not breathe, and could not be resuscitated. The mother was lying across the bed with her buttocks at the edge. I heard a dripping and noticed that she was bleeding freely. Examination discovered that there was a rent of the cervix almost to the cervico-vaginal junction. In passing my hand up into the uterus to liberate the placenta, it encountered a constriction of the womb at its middle, compressing the placenta at this point and preventing its descent and expulsion. I passed my fingers into the upper chamber, scratched the fundus, causing contraction of the upper chamber, expulsion of the placenta, and, in a very short time, even contraction of the entire uterus. The hemorrhage continued, and digital examination satisfied me that it came from the rent of the cervix. The nozzle of a syringe was pressed into the angle of the laceration and hot water made to flow against the bleeding surface until the bleeding was arrested. The patient was prepared for the night. She slept well and had no bad symptoms except retention of urine for five days. She was catheterized several times a day. On the second day I noticed that just within the introitus vaginæ there had been torn away a piece of mucous membrane of triangular shape and measuring about ¾ inch by 1¼ inches. Except the retention of urine, there was nothing abnormal after the first night. She was up on the tenth day. Her husband opposed the sewing of the cervical laceration on the grounds of a probable rupture at the next childbirth, and the extra expense for doctor's fees. His wife believed his view of the case, and nothing could change their opinion.

Remarks.—This patient did well in spite of an uncommonly severe and complicated labor, recovered in a short time, suffered no distress but that of a retention of urine, which was always relieved in time to prevent any annoyance, and all this without any medication internally or locally except ordinary warm hydrant-water injections to remove the discharges consequent upon the cervical-vaginal rents.

Case X.—Post-partum Hemorrhage due to Adherent Fibrous Placenta; Rapid Removal.—Mrs. H., married, German, multipara, was attended by me in her confinement. All went well. The nurse was holding the child as I sat by the bedside with my hand on the mother's belly, making pressure upon the well-contracted uterus and gently moving the belly wall over the fundus. The mother sighed; I gently reminded her that all would soon be over and she could then rest as long as she pleased. Very soon she yawned and I thought she would be sound asleep in a short time. Then I looked at her and noticed the "whites" of her eyes through her half-open lids; she had very pale lips, in fact they had been red a moment ago; and her face was very pallid. Then she sighed and yawned again and looked frightened, while I became suddenly alarmed for her welfare. Passing my hand to her wrist I found it quite cold. The uterus under my watchful hand was all that could be desired. The other hand found between her thighs a wedge-shaped clot filling the hollow formed by the buttocks, thighs and bed. It seemed fully one and a half inches

thick just below the vulva. Then I found that the placenta was entirely within the uterus; that it was stiff; that it and its membranes were adherent; and that the hemorrhage came from the uterine wall near the edge of the os, from which the placenta had become detached. By this time the patient was alive to her danger. I called her husband to my aid, having him crowd my hand down toward the pelvic floor so as to help force out the placenta while I loosened it from within. After about forty seconds' most vigorous clawing, I had loosened the placenta, and with his help and the uterine contractions, it was expelled. The pain to the patient must have been agonizing, for it caused her to shriek in a way that perfectly astounded me—it was almost deafening. It only lasted during the removal of the placenta. She had no further trouble except that due to loss of blood, and she left her bed in less than two weeks. The placenta was very firm and dark-gray in color, having undergone a marked fibrous degeneration. At its lower edge was a surface about as large as a silver dollar, and circular in shape, that had a normal placental appearance, and this spot was the source of the hemorrhage

Remarks.—This case proves that a well-contracted uterus containing a placenta is not an absolute indication that all is safe. If hemorrhage occur in a dark, windowless room, as this one was, it is best to keep one hand at the vulva, or at least pass it there at short intervals, to guard against sudden surprises. It is always well to watch your patient's pulse and the color of her lips until she can be left for the next call.

—The appointment to the vacant chair of Medicine at the University of Vienna has not yet been made. The names mentioned in connection with it, in addition to that of Professor Schrötter, are Professor Riegel of Giessen, Dr. Mossler of Greifswald, Dr. Quincke of Kiel, and Professor Rembold of Vienna.

—The *British Med. Journal*, Dec. 8, 1888, says that chocolates, confectionery, dried fruits, cheeses, and other food products are very often wrapped in what appears to be, and is described as, tin foil, but it is really an alloy, containing a good deal of lead. This dangerous practice is now prohibited in France, and the tin foil destined for wrapping food-stuffs and confectionery must be composed of "fine tin," that is, an alloy containing at least 90 per cent. of tin.

THE CONJUGAL QUESTION.

BY W. C. EUSTIS, M.D.,
FARMINGTON, MINN.

Almost every sane person with rare exceptions expects to enter the married state sooner or later, and the question naturally arises: what are the impelling motives to seek a life union with one of the opposite sex?

It is generally conceded that the sexes were intended to contribute through conjugal oneness to each other's happiness as well as to the multiplication of their own species. If the wedded state were always entered with correct views of what it implies, and with a sincere purpose to live afterward properly and naturally, all would be well; but when it is once entered, disappointment often arises in unexpected ways. One or both of the contracting parties find that the new relation has cares and responsibilities which were, perhaps, not even thought of. If both are disposed to be just and reasonable, all may yet be well; but a fretful, fault-finding spirit too often invades the household and paves the way for multiplied troubles. Sometimes the wife finds herself unable to meet the demands of her husband for the sexual act; while on his part, regarding the act as one of his marital rights, he may fail to apprehend the damage it may do to his wife, and, if he is not morally well balanced, he may grieve her by neglect or even obtain sexual gratification in the arms of a courtezan or a mistress. He may know that such infidelity is both wrong and debasing, and yet excuse himself on the ground that he has a sexual nature imperious in its demands, and that, since the woman whom he married can not fully satisfy it, nothing is left him but to seek elsewhere for what is wanting in his own home.

A partial remedy for marital infelicities is to be found in marrying stronger and healthier women. No mother ought to be ignorant of the natural demands that will be made on her daughter, and mothers, of all persons, ought to object to their daughters' marrying, unless confident that they are capable of meeting the sexual requirements of the married state. Unfortunately, instead of this being the case, there is apparently no attention paid to the matter, but delicate girls and feeble women marry without hesitation men of powerful physique and men whose very physiognomy bespeaks the strong sexual passion of their natures. So long as people continue to wed those who

are not their sexual equals, so long will trouble arise from these unequal unions. It is of little use to demand of men that they shall limit the gratification of their sexual appetite to the strength of the weaker vessel; for few men are reasonable and just enough to do this, and husbands who are married to sexually weak women feel as though they had been defrauded to some extent, and this feeling often makes them less considerate than they ought to be of the comfort of those who have disappointed them.

Look at it as we may, unless a woman is fully able to satisfy the sexual appetite of her husband, she had far better never take part in the conjugal relation. It is only too true that men often regard women merely as a natural means of gratifying the sexual appetite, and on the other hand women of respectability often encourage this view in ways calculated to appeal to the animal passions of man: forgetting apparently, that men rarely place women on a higher plane than they place themselves upon. It is notoriously true that man is more particular before the world in regard to his female society than is woman of male society. It is no uncommon event for a woman of refinement to wed a man who is suspected or even known to be unchaste. If women made good character an invariable condition of marriage, they would do more for themselves than men have ever done or ever will do in their behalf.

On the other hand, the ills that many women suffer in the married state are not wholly due to man. They ought to bear in mind that men have to be taken as they are, and if they do not like them so, they should not take them at all. No wife dreads anything on the part of her husband more than his marital infidelity, yet how little wives sometimes appear to think of some of the causes which lead to it. There are few husbands who do not like to be petted by their wives; and, while many do not deserve it, still there are others who do, but too often meet with fault-finding or indifference which gradually leads them to care little for, if not actually to hate, the real or prospective mothers of their own children.

Fallen women study the weak side of man's nature, and meet him with sexual gratification, petting and caressing to his heart's content. What wonder, then, that morally weak husbands sometimes grow weary of the conjugal yoke, and seek abroad what their own homes fail to yield them? A wife's imperfections are a poor excuse for a husband to prove false to his marriage vows; but in every age they have led to the fall of excellent men, and thus we may expect it will ever be. Should the time ever come when from childhood both sexes shall be properly trained for the relations and duties of mature years, then and then only may we expect the millennium of married life. The conjugal relation is a complex one, and its problems can only be satisfactorily solved by a proper training of both sexes for their respective stations in life The artificial state of the world socially is largely to blame for much of the married wretchedness that exists in every community. Too many wives look upon motherhood beyond two or three children with aversion if not with positive hatred. They declare openly that they prefer to sacrifice themselves on the altar of fashion or of some other god of this world than on the altar of maternity and of home. As a natural consequence of this condition of too many wives' minds, a large number of husbands find themselves joined to women who shirk in every possible way their maternal and housewifely duties, leaving to hirelings many of the sacred obligations that belong to them only, and cannot properly or successfully be assumed by any other. It can not be that such a state of things should exist without much domestic clashing. A quiet well-ordered home is an earthly heaven to a husband, even though he is possessed of no more than an average appreciation of the good and the beautiful, while the opposite can only exert a baneful influence.

Let woman take her proper place in the word's economy and keep it; let her ever insist on sound morals and a sound body in her future husband, and the conjugal question will be practically solved. But let no man or woman expect to violate natural laws and escape their penalty, for all such are surely doomed to disappointment.

—Dr. Joseph J. Kenyoun, in his report on the use of phosphorus as a disinfectant, made at the laboratory of the United States Marine-Hospital Service at New York, says that the conclusions from his experiments are that phosphoric pentoxide is a disinfectant to surfaces only; that it has no penetrating power, and is altogether unfit for fumigation of anything where penetration of the agent is desirable. He did not deem it worth while to pursue the subject further when it promised so little; therefore no observation on the spores of different microörganisms was made.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, Dec. 6, 1888.

Dr. T. M. Drysdale in the chair.

Dr. Wm. Goodell showed a

Recurrent Intraligamentary Cyst,

removed without entrance into the peritoneal cavity.

The patient, a woman 31 years old, at the age of eighteen had an ovarian cyst removed by Dr. Joseph Schnetter, of N. Y., who, in answer to a letter of inquiry, was kind enough to write the following description of his operation: "The cyst had no pedicle and was attached with a very thick mass of fibrous tissue to the right side of the uterus. This attachment being very vascular, it was necessary to ligature in several portions the parts representing the pedicle and to sew them into the incision of the abdominal integuments for the purpose of being able to control the secondary hemorrhage, if any should occur—which, in fact, soon took place, several days after the operation."

"Mrs. ——, after recovery, menstruated regularly through the cicatrix, and had an attack in New York similar to the one for which you are attending her at present. My opinion is that a piece of the lining membrane of the cyst may still be left in the cicatrix, causing an accumulation from time to time and opening the cicatrix."

"I should have mentioned that after the opening of the abdomen, the large omentum was found rolled up, forming a large tumor, including an abscess containing almost a pint of purulent matter. This was probably the sequence of two or three tappings of the cyst, preceding laparotomy."

On the 25th of last Nov., Dr. Goodell was called to see the patient by Dr. Thomas C. Potter, of Germantown. She was hectic, much emaciated, and bed-ridden, and was daily losing strength from a free discharge of pus, which escaped through a fistulous opening in the abdominal cicatrix. This he probed, but the instrument ran upward and inward, more in the direction of the kidney, than in that of the pelvis. So much blood followed the use of the probe that its use was not pushed very far. Under the cicatrix lay a tumor of some kind, which in front was hard and unyielding, but by bi-manual palpation it gave the sense of a very large pelvic abscess. Into this tumor the probe did not enter. The womb was fixed, the fundus being pushed over to the right. The fistula had opened early in 1885, and has lasted ever since. In Dec. 1886, the patient had a very severe attack of peritonitis, which kept her two months in bed, and it was after this attack that the tumor first appeared. The hardness of that part of the tumor which lay under the cicatrix, and the sense of fluctuation by vaginal palpation, so perplexed me that I wrote to Dr. Schnetter for further particulars, and his reply, which he courteously placed at my disposal, I have just read to you. On Dec. 1, I operated on her at my private hospital, and I must confess that no case ever puzzled me so much. The fistula was first enlarged so as to admit the finger. As this gave no satisfactory information the incision was lengthened in the old cicatrix to about four inches. This revealed a solid colloid tumor about as large as a cocoanut. It was firmly adherent to the cicatrix, and to the abdominal wall in front and to the left side. When the lateral adhesions were severed, a very large amount of pus escaped from the wound, and the hand now entered into a capacious cavity wholly shut off from the peritoneal cavity by walls of thick pyogenic membrane, which at the navel looked like a false diaphragm. Into this cavity the colloid tumor hung as if it were suspended; that is to say, while its upper and right lateral surfaces were firmly and closely adherent to the abdominal wall, its under or lower surface, free from adhesions, projected into the fluid of the abscess cavity. A short and slender pedicle running from the lower end of the tumor was lost in the pelvic floor of pyogenic membrane. Where this pedicle ended it was impossible to discover, as not a pelvic organ could be felt through the thick membrane; but it was closely adherent to the lower abdominal wall, from which it was detached before being tied and cut. The tumor was now cut open and its size lessened by digging out its contents with the finger-nail. When it was removed, free hemorrhage occurred from the broken adhesions. This was checked by Monsel's solution and by the free application of vinegar, a pint of the latter being poured into the cavity and plashed about the bleeding surfaces. This large cavity was then treated by the capillary drainage of Mikulicz—viz., by packing it with iodoform gauze. Since the operation the patient has done unexceptionably well,

the temperature being always normal and the pulse not more frequent than it would be in a patient as reduced as she is.

In reviewing this curious case it seems to me that the original tumor removed by Dr. S. was an intraligamentary cyst of the right ovary; that, as he suspected, a small piece of the cyst wall was left in that portion of the broad ligament which was made the pedicle, and sewed into the abdominal incision; and that, *pari passu* with the growth of this fragment of the cyst, an abscess had formed between it and its capsule of broad ligament, which formed the walls of the abscess. The four-inch incision into the abdominal wall did not open into the peritoneal cavity, but merely into a vast pus-sac. The tumor was therefore a recurrent intraligamentary cyst and wholly extra-peritoneal. The wonder to me is that this patient bore for so long a time so large an abscess without losing her life.

Dr. Goodell also showed an

Ovarian Cyst

which he had removed a few hours before, in which the characteristic green hue of necrosis was marked. Torsion of the pedicle occurred one month ago, and was characterized by severe abdominal pains and excessive vomiting. After this the woman gradually failed in health and lost flesh from chronic blood-poisoning. A few hours before the operation another attack of pain and vomiting took place. The cyst was universally adherent to the abdominal wall, intestines, and omentum. The pedicle, a very slender and short one, was so twisted as to stop all circulation, the cyst being nourished merely by its adhesions.

Dr. Goodell showed a specimen of what he deemed to be an

Extra-Uterine Fœtation.

A healthy woman, 33 years old, had been married 13 years without conceiving. Her catamenia had always been regular up to two months before Dr. Goodell saw her, when they were delayed for over two weeks. A few days before they reappeared, she was seized with a violent pain, "like cramps," in the pelvis, "shooting upward like knives." This was followed by syncope. Hypodermics of morphia were resorted to and she was left with a pelvic soreness that kept her in bed for several days. During the flow of this delayed period a second attack of pain occurred, analogous to the first, but not quite so severe. In about a week another hemorrhage came on. A few days later she had a third attack of pain and of syncope, which took place at night. A third hemorrhage now occurred, which was also followed three days later by a severe pelvic colic. This seized her as she was in the act of getting out of bed. The last attack took place on Nov. 18, and she was left for several days very weak and nervous. On the 25th, she consulted Dr. Goodell about the pelvic colics, irregular hemorrhages, painful defecation, and occasional pains running down the left leg. He found a small womb pushed forward and to the right by a boggy tumor, lying to the left in Douglas's pouch. The diagnosis of extra-uterine fœtation was made, its dangers explained, and an early operation insisted upon. Both the patient and her husband were so shocked by this discovery, and seemed to be so incredulous, that Dr. Goodell deemed it best for them to get the opinion of another physician. He sent them to Dr. Joseph Price, who confirmed the diagnosis. Very early in the morning of Nov. 29, while she was in his private hospital, a fifth attack of pain, with a "bursting feeling," aroused her out of a sleep. This was followed by faintness. At nine o'clock, about six hours after this attack, laparotomy was performed. As soon as the cavity of the abdomen was opened a large amount of black blood, of the consistency of thin molasses, welled out of the incision. Several knuckles of intestine were also forced out, which could not be wholly kept back during the operation. The right ovary was found, but the left could not be discovered. In its place was found an irregular cavity, within which was found a tumor about the size of an egg, containing within its sac layers of coagulated blood. It was attached to the broad ligament, which was tied and cut off. A very large number of old clots and shreds of fibrin were flushed out of the abdominal cavity by means of a syringe, six quarts of water being used for this purpose. A drainage tube was put in and the wound dressed with iodoform gauze. So much hemorrhage occurred later through the tube, that he spent several hours by the side of his patient, fearing it would be needful to reopen the wound. But, by dint of keeping the blood from collecting in the tube, the bleeding points were kept dry and the hemorrhage ceased spontaneously. The tube was removed on Dec. 3, and the patient has thus far had an uninterrupted convalescence. Dr. Goodell had not been able to examine the specimens carefully, but Dr. Baldy, who was present at the opera-

tion, had cut it open and he would like him to describe it.

Dr. Baldy said that the history of the case had been rather typical of extra-uterine pregnancy, and the escape of dark-colored blood from the abdominal incision at the operation seemed to confirm this opinion. The mass, which had been shown, was brought to the surface and cut away, after being tied. This was apparently all there was to come away, there being nothing left except a sac filled with old blood-clots, which sac was formed by adherent intestines and uterus and pelvic walls. The mass itself contained a semi-fluctuating tumor the size of a small egg, which he felt confident contained the fœtus, before it was opened. On being laid open it appeared like a large blood-clot, parts of which had undergone degeneration, presenting a mottled appearance. A small portion of normal tube seemed to run directly into this mass, and, as it reached it, spread its coats out over the mass. The ovary was nowhere to be found. He believed that the mass was blood-clot; but could not explain its occurrence. The fœtus was not found.

On motion of Dr. Baer, the specimen was referred to the committee on morbid growths.

Dr. Joseph Price read a paper on

Tubal Disease a Primary Cause of Intestinal Obstruction.

In reporting cases I have repeatedly called attention to the frequency of adhesions occurring between the uterine appendages and some part of the intestines, and my purpose in this brief note is to emphasize the importance of recognizing the danger of obstruction of the intestine arising from inflammatory conditions of the pelvic viscera. In glancing over the cases I have operated on during the past year, I find that in more than 15 per cent. there were noted "dense firm adhesions" between the intestines and uterus and appendages, malignant cases not included. In every case, with one single exception, as far as I could determine from the history, symptoms, and operative deve opments, the inflammatory conditions causing the adhesions originated in the uterine appendages. I do not intend to discuss the pathology of inflammations in the pelvis, nor to present statistic evidence, nor to cite numerous authors who have recognized these lesions, as Greig Smith and others, for the few general observations I desire to make. And first as to the form or kind of obstruction likely to occur. The inflamed serous surface of the diseased tube or ovary coming in contact with a loop of intestine or an edge of omentum, provokes inflammation there, and with characteristic promptitude these surfaces cohere. If the process is not severe and is of slight duration, these adhesions may disappear as promptly as they occurred. This is accomplished by the enormous absorptive power of the peritoneum and is hastened by the mild influence of the peristalsis of the bowel. If however the inflammation is severe, or assumes a chronic condition, these adhesions gain in extent and strength, and give rise to all the variety of conditions classified by Treves as "strangulations by bands." In most cases where these adhesions occur there is a history of constipation. The latter is probably due as much to the pain caused by defecation as to interference from the condition. Again, the pain is often so great as to mislead the physician into thinking that a more virulent inflammation exists than is actually present. But the pain is not always proportionate to the amount of mischief. I have seen cases in which a mere omental adhesion has caused most agonizing pain. For instance, I recently saw a case in consultation—a woman had had the appendages removed for backache, sometime before, and suffered excruciating pain especially on defecation. In this case the only lesion found was the omentum firmly adherent to the original incision. The omentum here was much elongated and the transverse colon was dragged below the level of the umbilicus. In like manner I have seen the omentum adherent over the entire pelvis, dragging the transverse colon so out of place that a twist or kink of the bowel could be very easily found. It is not at all rare to find the vermiform appendix glued fast to the uterine appendages, while almost any loop of the small intestine may become adherent to the inflamed pelvic viscera. As I have said, these adhesions vary in extent and density from those that will tear like wet tissue-paper to those so well organized that it requires the scissors to release them; and it is not rare in pus-cases for the bowel to be almost gangrenous about these points of adhesion, and, in fact, to tear through. That adhesions do not cause complete occlusion at the time of their formation oftener than they appear to is no reason for regarding them lightly, for Mr. Treves tells us that in the series of cases he studied the average duration of the interval between the causation and the obstruction was three years; the shortest period being five weeks and the

longest 21 years. In view of these general considerations it is hardly necessary to insist upon the release of the intestine wherever and to whatsoever extent adhesions exist. For, if the surgeon leaves adhesions when he closes the abdomen, he leaves a probable cause of future serious trouble. Louis reports a case in which an ovarian cyst when emptied by the trocar so dragged upon an adherent bowel that intestinal obstruction developed. I am inclined to believe that some of the deaths from intestinal obstruction after operation are due to leaving old bowel adhesions undisturbed.

Dr. Wm. Goodell said that his experience in ovariotomy led him to say that it is a mistake to postpone the opening of the bowels to a late period. He used to follow the old plan of not giving a cathartic until the eighth day, but he was confident that he had had death result from this practice in consequence of the formation of intestinal kinks from adhesions, making it impossible for the bowels to be moved. He now almost always gives an aperient or an enema on the fourth day, and earlier if any symptoms, such as vomiting and tympanites, present themselves.

Dr. B. F. Baer said that up to a few years ago he also had followed the plan of keeping the bowels confined after laparotomy, but now he had them moved on the second or third day—rarely as late as the fourth day. That good plan of quenching the thirst by allowing a pint of warm water to flow into the rectum, facilitates the passage of flatus and feces. He thinks it a mistake to give opium, as was formerly done. Intestinal obstruction is likely to result, as well as adhesions. But this question must be settled by the requirements of each case. He had a case four years ago in which very serious collapse occurred at the end of the second day. Stercoraceous vomiting occurred and large quantities of flatus were passed by the mouth, but none by the anus. These symptoms were thought to be due to obstruction, and reopening was considered but not done. The patient recovered, although she did not pass flatus for five days. Should such a case occur again he would open the wound, and he would have the endorsement of most operators in so doing. Large doses of salines are advised in such cases, but he wondered if there was not some danger of rupture of the bowel in these cases of adhesion after serious operations, and he related the following case: An ovarian cyst was closely adherent to the large intestine for a considerable distance: On the evening of the 3d day after operation, symptoms of a septic peritonitis developed. A large dose of Epsom salt was given. The next morning the general condition was better, but he found that liquid feces were flowing from the wound. He reopened the wound and tried to find the point of rupture and close it with sutures. Even after having enlarged the original opening, the ruptured point could not be found on account of its depth in the pelvis and the amount of lymph thrown out. He then closed the wound, without drainage, but freshened the surface of the drainage tube-tract and closed it, hoping that the freshened edges would unite. In two days fecal matter again appeared, symptoms of collapse developed and she was expected to die. She, however, finally recovered. The fistula has entirely closed. The lesson he learned from the case was, that when rupture of the bowel occurs under similar circumstances the best plan is to let it alone. Dr. Price had referred to two cases in which he reopened the abdomen for pain and found the omentum adherent to the line of incision. It is unfortunate that we do not know of some means to prevent these adhesions, but it is a wonder that they do not more frequently occur in the line of the incision and to the raw surfaces left after separating adhesions. He knew of no better way to prevent this accident than by the early use of laxatives. Probably much of the pain complained of after operations is due to adhesions, and it is unfortunate that we should be called upon to reopen the abdomen in order to release them. Would it not be wise to give nature time to adjust matters, since there is danger of the formation of other adhesions from the second operation?

Dr. Wm. L. Taylor read a paper on

Fixed Uteri.

In looking over my case-book I find the remark "uterus fixed" so often noted, so often helplessly, but I trust not hopelessly, underscored, as much as to say "there again," that I fain would ask, how many of these cases were in their inception recognized as cases of peritoneal inflammation? In a number the note is made: "patient had attack of inflammation of bladder." "Inflammations of the bowels" has been of alarming frequency, whilst "congestions of the liver," makes me wonder at the special degree of sensibility of that organ in women. In one case in which there was eventually a fatal relighting of a former peritonitis, the

original trouble was noted as an attack of "wind colic of the bladder." If these attacks of peritonitis with their resultant lymph deposits are so grossly misnamed, is it not more than likely that the abortion, or at least the curative treatment, is as far afield? In a series of cases in which the lymph deposit seemed to be the most diffused a positive history of an active and acute inflammatory trouble could not be obtained. There was only the history of a continued abdominal pain and tenderness, dating from an abortion, from heavy lifting, seldom from normal labors, and presumably never from gonorrhœal infection: seldom—I might say never—have I had perfect success in my efforts to trace the cause to this infection. The history of the husbands, as to the existence of a gonorrhœa or gleet, at the time of commencement of pelvic trouble, is in the vast majority of cases worse than uncertain. In several of the subacute cases the only ascribable cause appeared to be, indirectly if not directly, the effort to prevent conception. Freedom from the possibility of at least paternal cares, leads to an amiable weakness, and coition follows coition in quicker succession than the law of conservatism would recognize, and, in addition to the menstrual congestions, which now even occur sooner than is normal, without the restful periods of pregnancy and lactation, congestion and inflammation of the peri-uterine tissues follow. I am inclined to believe that this is as immediately the cause of the fixed uteri, the thickened and enlarged ligaments and tubes and tender ovaries, as is gonorrhœal infection, even in prostitutes. Where the deposit of lymph was more localized or larger in quantity, seeming as if it had been poured out quickly and had by gravity centered itself around the uterus, there were the histories of acute, well-marked attacks of cellulitis or peritonitis. The causes were difficult labors, with badly lacerated cervices, these lacerations extending through into the cellular tissue, and also criminal abortions. In these cases it is impossible to say how often traumatism and how often septic poisoning was the exciting cause. Catching cold while menstruating, falls and various other accidental causes were among the number.

The average physician, as soon as the patient is up out of bed, shakes himself by the hand and says: "I have cured my patient." But he has not. There is still the important sequel to deal with—the lymph deposit. In fully three-fourths of all the cases the body of the uterus has become fixed in retroflexion, even in multipara. Just as soon as the uterus feels the stimulus of congestion or inflammation of surrounding tissue, it becomes turgid and heavy, and sinks decidedly lower in the pelvis until the cervix is near the vulvar orifice; and following the curve of Carus, the fundus is retro-displaced. Here it is, as it were, frozen in, fixed immovably. All around it is a mass of inflammatory lymph becoming more dense and resisting as organization advances. In the centre of this the sound probably indicates the uterine body, with a measurement of 3½ inches. The cavity is tender and the cervix softened, congested with venous blood. Now this deposit varies greatly in quantity as the inflammation has been limited by judicious treatment or by nature alone, or has been allowed to involve a great extent of peritoneal surface. The possibility of determining the amount of lymph deposit and the degree of fixation by bi-manual examination seems to me to be one of the few certainties in gynecological practice. A uterus which is low in the pelvis and which cannot be raised to the normal line, and a fundus which is retroflexed and cannot be reposited, with the other evidences bi-manually of thickening and deposit, cannot but point to the certainty of previous inflammation. A sterile uterus and a fixed uterus seem to be almost synonymous. The ovaries and Fallopian tubes have become merely painful spots and useless for the purpose of conception; and should the patient conceive, the uterus seems unable to enlarge, and expels the fœtus for want of growing-room. When I find a young married woman with evidences of a former peritonitic inflammation, I am very guarded in my promises for her future fertility. Backache, ovarian pains, and headache, metrorrhagia or menorrhagia, profuse leucorrhœa, bladder and bowel irritation, and a thousand and one nervous phenomena mark a very unenviable period in the patient's life. Hysterical, fretty and worrisome, she is a burden to herself. The ovaries have prolapsed with the uterus and are imbedded in and virtually strangulated by surrounding lymph. Menstruation, which before was painless, now gives place to severe dysmenorrhœa. The pain is different and more wearing than that due to simple stenosis. It begins several days before the menstrual flow as a more or less steady, throbbing, sickening pelvic pain, extending down the inside of the thighs. As soon as the flow is established this pain

gradually gives way to the never-ending backache and pelvic dragging. Sometimes there is pre-menstrual nausea and vomiting, due undoubtedly to ovarian pressure.

In nearly all the cases there is fungoid endometritis as a result of the continued uterine congestion; hence the metrorrhagia or menorrhagia, notwithstanding which the uterus seems to become more congested and more tender.

The need of shortening these attacks of pelvic peritonitis, aborting them if possible, can only be appreciated by those called upon frequently to treat the sequelæ. In traumatic cases, where there is no reason to suspect septic influence, as soon as the usual symptoms of peritoneal trouble present themselves, the lower bowel is thoroughly moved by an enema of sweet-oil and turpentine; the patient's hips are then decidedly elevated by pillows or by elevating the foot of the bed, so as to drain off the pelvis as much as possible, and also to keep the pelvic organs from prolapsing. From 20 to 30 grains of chloral by the bowel, and from ⅛ to ¼ grain of morphia hypodermically are given. A thin flannel binder is applied loosely, and on that, over the abdomen, an ice-bag is placed and kept there, not one hour, but for hours. A febrifuge is given, and the ice-cap with antifebrin if the temperature reaches 102°. Where there is evidence of septicæmia, with the clammy skin, the sunken eyes, the central heat, I have the bowels thoroughly evacuated by divided doses of calomel and soda, and administer quinine in 10 grain doses every four hours, until my patient complains of tinnitus. To the abdomen I apply a large turpentine stupe, followed by a light poultice. The hips are elevated and if there is positive need for an opiate a vaginal suppository of aqueous extract of opium, grains 3, extract of belladonna, grains 1½, is used. If these attacks are thoroughly treated the amount of lymph thrown out is small and probably will be absorbed almost as rapidly as it was thrown out. But we meet a case which was treated by "the other doctor around the corner," and the uterus and its appendages are, as before described, imbedded and immovable. Now what are we to do? The great object is to get rid of as much of this effused matter as we possibly can. The older and more thoroughly organized this becomes, the less chance there is of rapid and complete absorption. So the moral is, Commence early! It is going to do one of three things: undergo absorption, break down and form a pelvic abscess, or become organized, acquiring an adventitious circulation. When I meet a case of recent or comparatively recent deposit, in which I can have my directions enforced, I am confident of success. I commence treatment by correcting the digestive tract, getting the stomach, liver and bowels in better condition, and surface circulation stimulated by warm baths and frictions. I then give the corrosive chloride of mercury with the iodide of potash, commencing with small doses frequently repeated and gradually increasing the dose and lengthening the interval. In the use of the bichloride and iodide I have had marked success, much greater than in cases treated with iron and bitter tonics, the same local treatment being used in both. Locally, I rely upon the abdomino-vaginal galvanic current and gentle or more decided uterine massage, as there is great or little tenderness. I prefer uterine massage in cases of long standing, in which the tenderness has disappeared, but I still use it carefully when there is tenderness; I find it beneficial. Every other day, or twice a week, I make steady pressure upon the fundus of the uterus with the index finger of my left hand in the rectum, and upon the cervix and body of the uterus with the right index finger in the vagina. This pressure I keep up for two or three minutes, gradually trying to force the body upward and forward. Then efforts at lateral movement are made for the same length of time. This massage I follow with the continued galvanic current, using the abdomino-vaginal method. For the breaking down of pelvic lymph, I have not used electro-puncture, preferring the slower and as certain absorption by the stimulation of pelvic circulation. Where there is tenderness I use the positive pole in the vagina and the negative over the abdomen for the first three or four applications, and it is marvelous how speedily this tenderness disappears. I then reverse the poles, using the negative with a ball or small crescent-shaped electrode in the vagina. These seances, including the massage, last for about fifteen or twenty minutes. The strength of current averages about twenty-five to thirty milliamperes. After this is over I frequently pack the fornix with wool, introducing a small ring pessary to keep the wool as much as possible in position. After I gain a certain amount of mobility I introduce a Smith-Hodge pessary, small at first, increasing to a more suitable size as the uterus rises to the normal line. Tincture of iodine to the fundus of the vagina, flying blisters and

the hot water douche I have tried faithfully, with uncertain success, but I have not tried them so often since I have found such positive relief from galvanism. In the cases of much longer standing, I acknowledge that all I can get from galvanism sometimes is the relief from pelvic pain. Can we get anything more from other treatment? Out of a series of 20 cases, in which galvanism and massage were employed for the purpose of relieving pelvic soreness and pain and inducing mobility of the uterus, twelve patients were discharged after an average of twenty applications, each sufficiently improved to need no after-treatment. Four are improving under treatment, and four disappeared after one to five applications. In over one-half of these total cases, prior treatment had been faithfully tried before galvanism was resorted to.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 20, 1888.

The President, A. Jacobi, M.D., in the Chair.

Dr. Thomas E. Satterthwaite read a paper entitled:

A New Study of Lobar Pneumonia, with Deductions from an Analysis of 56 Fatal Cases.

Epidemic pneumonia, he said, does not prevail to any great extent at the present time, yet a certain number of facts sustain the theory that the disease is occasionally epidemic.

His paper treated of lobar pneumonia in its primary and secondary forms; the first form he called acute lobar pneumonia, and the other, secondary pneumonia.

But to avoid obscurity he mentioned the principal types of pneumonia, which are acute lobar pneumonia; secondary lobar pneumonia; embolic lobar pneumonia; bronchial lobular pneumonia; and the interstitial pneumonia of heart disease.

Acute lobar or croupous pneumonia is the most common form. In 100 fatal cases, taken from his hospital and private records, the several varieties were represented as follows: Acute lobar, 36 per cent.; secondary lobar, 19 per cent.; bronchial-lobular, 20 per cent.; interstitial of heart disease, 7 per cent. He has found it most common in males. It is for the most part a disease of middle life, and occurs almost altogether in northern and middle latitudes. When it originates in one lung it usually selects the right, and in his cases commenced in a lower lobe.

In the stage of engorgement the whole lung tissue is increased in volume, infiltrated with a serous fluid, with more or less transudation of blood from the vessels. In the second stage, or stage of red hepatization, the lung is of a deep red color, unyielding to the touch, and difficult to distinguish from an inflamed liver. It contains little if any air, and almost no fluid. Its cut surface has a granular and dull aspect, each speck corresponding to an air vesicle or cut bronchiole filled with a firm pellet consisting of blood cells and epithelium mixed with fibrine, which hold all firmly together. In the third stage, that of gray hepatization, the reddish tint yields to a dirty gray, at first tinged with brown, and then with yellow; the tissue is softer, and on pressure exudes a small amount of fluid; the walls of the blood vessels are studded with leucocytes; in many cases there is dark pigmentation of the interlobular spaces. The lung may weigh sixty ounces.

In Dr. Satterthwaite's experience the order of the symptoms is as follows: One, pain, prostration, and cough; two, a severe chill; three, nausea; four, rise of temperature. Chilly sensations may take the place of a severe chill. Within a few hours the temperature commonly reaches 103° or 104°. An early sign, though seldom the earliest, is fine crepitation heard only during inspiration. Occasionally this sign lasts the full course of the disease. As soon as the second stage begins there is dulness on percussion, with bronchial breathing and bronchophony, and also increased vocal fremitus. In the fourth stage, that of resolution, the returning crepitant rale is heard.

The author is inclined to think that the locality of the affection, whether in the upper or lower lobe, does not influence the production of cough or affect its character. In old people cough may be absent. The expectoration is peculiarly tenacious and variously colored. The characteristic prune-juice color is sometimes absent, and is replaced by a red, black, or green color; or the expectoration may be colorless. The characteristic sputum of pneumonia has three qualities: color, consistence, and coalescence. It may appear on the first day, or not until the third or fourth. It is not always present, and may occur occasionally when no pneumonia exists, as in nasal or pharyngeal catarrh with hemorrhage, or in acute laryngitis.

Diarrhœa is often present, and so are

nausea and vomiting. The urine is often scanty. Albuminuria is common, and is usually most marked at the height of the disease. There was kidney trouble in 41 per cent. of his cases; in 5 per cent. of these chronic kidney trouble of long standing existed; in only 8 per cent. was it shown by clinical and post-mortem evidence that there was no urinary implication. The greatest danger occurs in an exacerbation of an old kidney affection.

Little has been added to our knowledge of the clinical aspects of pneumonia since the studies of Laennec. In the stage of engorgement we may expect to find dulness, but we do not. Grisolle found in this stage loss of elasticity in the chest walls, especially when percussed in the supra- and infra-spinous fossæ. The crepitant rale was regarded by Laennec as the first pathognomonic sign. It is produced by fluid matter passing into the vesicles of the lung. In some seasons it is rarely heard; in old people it may be replaced by a coarse crepitant rale. Fine crepitation may be heard in other types of pneumonia, in pulmonary phthisis and syphilis, and even in bronchitis.

Prolonged expiration precedes tubular or bronchial breathing. Bronchophony and metallic voice, when considerable area of dulness exists, are also signs.

Pain is most frequent in the region of the nipple; next, at the base of the lung. It may be felt at any part of the chest. It is due to pleurisy. The pulse is usually 100 or more, and may reach 160. Jaundice is not very infrequent, delirium is common. Coma occurred in three per cent. of his cases; it is often uræmic. At first the respiration rises from 22 to 36 per minute, but within two days it may reach 40, 50, or 60.

Inflammation of the lower lobe seems to produce more oppression than inflammation of the upper.

In children the temperature reaches a greater height than in adults. It rises one or two degrees at night, and falls in the morning. The highest temperature in his cases was 108°, the lowest, 100.2°; in ten cases the highest average temperature was 104.3°. The crisis usually occurs between the fifth and seventh days. Unless there are unusual complications or sequelæ it never occurs later than the fourteenth day. The immediate cause of death is usually heart failure from prolonged and exhaustive work, or from the influence of poisoned blood on the nerve centers.

In speaking of the etiology, Dr. Satterthwaite quoted Sturges's opinion that it was produced by cold, dry, penetrating winds; some later writers, however, think cold an infrequent cause. Twenty-two per cent. of his own cases were ascribed to exposure to cold. The disease seldom occurs during the warmer months. Occupation has little bearing on the causation. Regarding the influence of microörganisms, it would be necessary, to prove that they are a cause, to show that a pure culture inoculated in the blood remote from the lungs would produce lobar pneumonia; but experiments have almost always failed in this respect, and when the lung itself has been inoculated lobular, not lobar, pneumonia has commonly resulted.

The pleura is always involved except in the rare instances when the inflammation remains central. A comparatively frequent complication is pericarditis; a more important complication is disease of the kidneys. The spleen is apt to be enlarged, and there is catarrh of the intestinal tract. True abscess of the lung is rare. Gangrene was noted in his cases. He does not believe phthisis could ever develop from acute lobar pneumonia.

The question of mortality, he said, has given rise to much dispute, largely because of indefinite statistics. Its discussion, to be of value, requires a knowledge of the variety; the patient's age; the general character of the attack. At some seasons the mortality is greater than at others, notwithstanding the same general treatment. Statistics before the middle of the present century give a mortality of from 16 to 55 per cent. Just before the middle of this century Skoda published statistics tending to prove that pneumonia is a self-limited disease. About 1842 Fleischmann, a homœopath, had a mortality of less than 6 per cent., which set other physicians thinking, and gradually led to less heroic treatment. The fact that the mortality varies in the hands of the same physicians shows that each case stands by itself. Dr. Satterthwaite's own experience shows that the expectant plan of treatment is best The causes of death show what should be the direction of treatment. It should not be the reduction of temperature so much as the sustaining of the heart and obviating renal complications. The author has been led to believe by post-mortem studies that antipyretics not only weaken the heart's action, but also have some unfavorable action on the kidneys. Every case of acute lobar pneumonia should be

treated by itself, and the indications met as they arise. He has often seen benefit from copious repeated cuppings in sthenic cases. In less vigorous persons relief often follows cold water applications. In defective hepatic action relief has come from large doses of mercurials. In weak heart patients have been carried through with alcoholic stimulants. In renal complications marked relief of pulmonary symptoms has followed remedies directed chiefly to the kidneys.

The author then passed to the consideration of secondary lobar pneumonia. This subdivision had been recognized by the old French school. His views of it are based upon 19 of his recorded cases. Without committing himself to an opinion as to their etiological value, he has found the antecedent conditions as follows: nephritis in 5; alcoholism in 2; phthisis in 2; burns in 2; rheumatism in 1; fracture of the ribs in 1; hypertrophy of the heart in 1; pleurisy with effusion in 1; pericardial effusion in 1. Contemporaneous affections were present as follows: abdominal dropsy in 1; pericardial effusion in 1; gangrene of the extremities in 1; aneurism of the aorta in 1; bronchitis in 2; syphilis in 2; endocarditis in 2; hydrothorax in 1. Cases in which there was a suspicion of phthisis or syphilis were not included.

Secondary pneumonia is usually insidious. Chill is frequently absent, and when present is not severe. Difficulty in breathing may not be marked. The crepitant rale is heard as a rule. The temperature rises rapidly, as in acute lobar pneumonia, but averages somewhat lower in range. The pulse often rises sharply at the outset, but averages lower than in the acute form. Bronchial breathing and dulness may be the most decided symptoms, and in his experience they have been the most common. The expectoration is apt to be scanty and afford little help in diagnosis. Renal symptoms are likely to be more prominent than in the acute disease. There is a decided tendency to suppuration. The duration is about the same as in acute pneumonia, but the crisis is likely to come earlier. The causes of death are about as in acute lobar pneumonia, and indicate the treatment.

—Dr. Guerra Y. Estape, according to the *New Orleans Medical and Surgical Journal*, Dec., 1888, regards the local application to the larynx and pharynx of a 10 per cent. solution of resorcin as the best treatment of whooping-cough at present known.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, December 12, 1888.

The President, J. Solis-Cohen, M.D., in the Chair.

Dr. John H. Packard read a paper on

Notes of a Successful Case of Laparotomy for Injury by a Circular Saw.

Charles Brown, aged twelve years, was brought to the Pennsylvania Hospital, September 24, 1888, having fallen against a circular saw in rapid motion. The accident occurred about one mile from the hospital.

On his admission, the ascending colon and about two feet of the small intestine were protruding from a wound four inches or more in length, nearly vertical, on the right side of the belly, some two inches from the middle line. The mass was tightly grasped in the wound, so that access of air to the peritoneal cavity was prevented. The boy was in a condition of marked but not excessive collapse.

He was etherized, and the parts antiseptically cleansed. The bowel was then carefully examined. Three wounds of the intestinal wall were detected; one involving the entire thickness, the other two the peritoneal coat only. At several points the omentum had been wounded, and the mesentery was cut in two places. The boy's woolen clothing had been torn by the teeth of the saw, and a great many minute shreds of the stuff deposited on the surface of the protruded mass.

The three intestinal wounds were carefully sutured with very fine silk, after the method of Lembert. All the bleeding points were secured with fine carbolized catgut. Some ragged portions of omentum were similarly tied and cut off. Attention was next given to the cleansing of the peritoneal surface from all the bits of woolen threads deposited on it; a very tedious process, occupying more time than any other part of the operation.

In order to return the protruded mass it was necessary to enlarge the wound somewhat; after which reduction was accomplished without difficulty. After irrigation of the peritoneal cavity, the edges of the wound were brought together with silkworm-gut sutures, secured by shot. A glass drainage tube with a closed and rounded end was inserted, and the usual antiseptic dressings applied, with a flannel over all.

Every two hours the cotton rope filling the tube was removed, and suction was made with a hard-rubber syringe with a long nozzle, so as to prevent any accumulation of secretions.

Reaction took place very favorably; the boy had only very slight pain, but some nausea and vomiting.

The nausea and vomiting continued all next day, subsiding toward evening. A free movement of the bowels occurred, and I learned later that an attendant, just after the boy's admission, had given him by mistake ten grains of blue mass, intended for another patient. As soon as the stomach became quiet, the administration of prepared milk and beef-tea, alternately every two hours, was begun.

On the 28th (the fourth day) there was only a slight yellowish discharge from the tube.

29th. The glass tube was removed, and a soft rubber one substituted for it. Solid food (milk toast) was given.

30th. He ate an egg and some chicken-broth.

A day or two after this the tube was removed, and a few days later the sutures.

For some two weeks after this the boy was kept in bed; he was allowed first to sit up in bed, and then to get up and walk about.

On October 31, thirty-seven days after the injury, he walked into the clinic-room; and on November 12 he was discharged, with directions to wear a binder for some time, and to report to us before dispensing with it.

I should have mentioned that, after the spontaneous movement of the bowels on the second day, an enema of turpentine and sweet oil was administered about every third day until his dismissal.

Certain features of this case may be briefly commented upon. The boy's youth was, of course, in his favor. He was stout and healthy, although his surroundings had not been, by any means, hygienic. But there was one circumstance of special advantage—the fact that the protruded mass quite filled up and plugged the wound in the abdominal wall. Besides this, the wounds were all of small extent, and no large vessels were divided. The presence of the almost innumerable shreds of soiled woolen clothing on the peritoneal surface was of course an element of danger, only to be set aside by the utmost care and patience in their detection and removal.

It would scarcely be fair to conclude this report without acknowledging the assiduous care and attention, and the skill in manipulation bestowed upon the case by Dr. Walter D. Green, the resident surgeon, who first had charge of it, as well as by his successor, Dr. Harvey Shoemaker. Much of the credit of the favorable result attained belongs fairly to these gentlemen.

[The patient was shown to the Society and examined by the members.]

Dr. Joseph Price, in opening the discussion, said: The fact that the protruding intestine completely closed the wound had a great deal to do with the successful result in this case. We know that undue manipulation and prolonged and needless exposure of intestine are frequent causes of shock and death; this fact is beautifully illustrated in needlessly prolonged operations. I never could understand the vicious do-nothing policy of ambulance surgeons in these cases of abdominal incised wounds. The ambulance surgeon should be prepared and instructed to act promptly in such accidents. Promptitude is everything. A pitcher of warm water and a few threads might save lives that are lost by carrying the patient untreated, with the intestines exposed, covered by filthy clothing, to the distant hospital, there to wait for the chief to arrive before anything is done. I recently read of a case of a man who was accidentally eviscerated while hunting alone in the backwoods. Someone found him with the intestines protruding and covered with dirt, and carried him to the nearest brook, washed and sewed him up. He was also fortunate in *being away from opium* and from meddlesome nurses and officious residents of a general hospital, and he recovered. The strictest simplicity, absence of opium and of milk, indeed of all food till the patient asks for it, except in greatly exhausted cases demanding early support or stimulation, will give the happiest results.

I give plenty of fluids, toast water, barley water, stimulating enemata of beef-tea, with perhaps a little whiskey if needed, and enemata of water to relieve thirst. We know how difficult it is to prevent hemorrhage in ether nausea. Careful preparation for the operation by the free use of salines will minimize the ether and bowel disturbance. I am satisfied that the free use of the salines is of greater importance *before* operation than after in abdominal work. The unintentional administration of blue mass in this case of Dr. Packard's was a happy accident and helped recovery.

I wish particularly to congratulate Dr. Packard upon the excellence of the toilet,

the care to secure perfect cleanliness under such difficult conditions, and the perfect drainage. The careful removal of all foreign material from the bowel, free irrigation, and perfect glass drainage in two desperate cases have given him a triumph in two cases of abdominal work.

Dr. Packard: I must say a word in reply to Dr. Price in defense of "my friend opium." You remove a tumor; all goes well until water is injected into the abdomen. Pain ensues immediately. You give a grain of the extract of opium by the rectum, when the pain disappears, the patient goes to sleep and wakes in comfort. Are you not justified in attributing this to the opium, and relying upon the same measure in similar cases?

Of course it would be a great mistake to treat all cases of peritonitis with opium. The saline treatment is proper in suitable cases, and saves many lives. So may we say of opium in suitable cases. The error is in exclusiveness, whether in the one direction or the other. We must use our judgment in individual cases, and prescribe in view of all the conditions present.

In this case I think nothing would have served my patient as the one grain of the extract of opium did. It was not a case of peritonitis, however, and I did not so regard it. But suppose some enthusiast in salines had ticketed the case peritonitis and immediately administered purges? I hardly think such prompt relief would have been afforded.

I would like, while on this subject, to mention a measure which I have employed for many years, and which has repeatedly seemed to me to avert threatened peritonitis, and that is the application of a dozen leeches to the abdomen. After operation for stone especially, as well as in other cases of traumatism, marked benefit has been derived from the adoption of this plan.

Dr. John H. Packard read a paper on

Tumor Probably of Uterine Origin, Attached to the Small Intestine; Removed by Laparotomy.

For the following notes I am indebted to the kindness of Dr. L. I. Blake, resident surgeon to the hospital. It is due to him also that I should acknowledge his skill and attention in dressing and caring for this patient.

Kate M., native of Ireland, aged twenty-six, domestic, single. Admitted to St. Joseph's Hospital November 13, 1888. Family history good. Personal history also good, with the exception of an ill-defined attack she suffered from three years ago, probably resembling in some points the present one, and which was pronounced by her physician at that time to be intestinal inflammation of some sort.

She had been examined by two physicians before admission into the hospital. The first stated that she had inflammation of the womb, while the second led her friends to believe that she was pregnant.

On admission, she stated that she had been suffering for three weeks, getting worse gradually. On examination her abdomen was found to be enormously distended, and exquisitely tender to the touch. Constant pain was felt throughout the greater portion of the trunk. Temperature 101° F.; pulse 100 and moderately strong. There being neither history of traumatism nor marks of violence, a vaginal examination was made, but no abnormalities noted. Her menstruation was established at fifteen, and has always been regular. When pain was sufficiently relieved to permit manipulation of the abdomen, distinct fluctuation was elicited, and in the left ovarian region was an area of dulness, which, though slightly variable, was not obliterated when the patient was turned on the left side. Deep pressure on this spot detected a hard mass which receded from the touch, but returned, the hand being kept in position. Owing to the extreme tension of the abdominal walls it was impossible to ascertain anything as to its nature or attachments.

The tympanites and ascites failing to respond to medicinal agents, the patient growing weaker, and at the end of three weeks the respiration being interfered with, an exploratory incision was decided upon.

The patient being in tolerably fair condition, the operation was performed by Dr. Packard on Saturday, December 8th.

The peritoneum was found to be very much thickened and congested, its appearance being scarcely distinguishable from that of intestine.

After removing five or six quarts of clear serum from the peritoneal cavity, the incision was enlarged, revealing a growth attached to a knuckle of intestine in the lower segment of the abdominal cavity to the left of the median line. This tumor, a little larger than a fœtal head, was hard and dense in structure, weighing one and a half pounds; encapsulated and attached by a narrow pedicle, little more than an inch in breadth, which seemed to be a redundant portion of the capsule thrown around almost the entire circumference of the intestine. This was

carefully dissected away from the intestine, and all bleeding points ligatured.

The peritoneal cavity was irrigated thoroughly with a solution of the bichloride of mercury, 1 part to 15,000 of distilled water. The peritoneum and abdominal walls were sutured separately, the former with catgut, the latter with silkworm-gut. A glass drainage tube, perforated and closed at the bottom, was placed in Douglas's pouch, and the wound closed and dressed.

The operation was done under full antiseptic precautions. The patient showed considerable shock after the operation, from which she rallied slowly. It was accompanied by persistent vomiting, which was relieved by one drop of creasote every two hours, administered in syrup of vanilla. A peculiar temperature was exhibited during this period, the same thermometer registering successively in the mouth 96⅗°, in the axilla 97⅘°, in the rectum 101°. During the first twenty-four hours there was not sufficient discomfort or restlessness to call for anodynes. Up to this time, about six ounces of bloody serum had been drained from the cavity. Four ounces of warm distilled water were then injected through the tube, and allowed to remain four or five minutes. Since that time, during the last seventy-two hours, not more than three ounces of serum have been removed, and scarcely tinged with blood. A short time after the warm water was removed, the patient complained of sharp, shooting pains, with marked tenderness over the abdomen. These became so severe as to require a suppository of opium (one grain), which soon induced a quiet sleep, with no return of pain on waking.

Thirty-six hours after the operation a slight but persistent cough was developed, probably due to hypostatic congestion, since change of position gave relief.

During the last three days the temperature taken in the mouth has not risen above 100⅖°, the pulse varying from 90 to 100.

Ever since the operation the patient has evinced a strong craving for food, giving milk the preference above anything else.

[The subsequent progress of this case has been very favorable. On the 11th of December (the sixth day) the glass tube was removed, and a soft-rubber one substituted, until the 17th, when it was dispensed with. On this day she had a spontaneous and quite natural movement of the bowels.

Suppuration occurred in the suture tracks, probably from insufficient preparation of the silkworm-gut used. On the 24th of December (the sixteenth day) she was allowed to sit up in bed, the wound being quite healed.—P.]

Dr. Osler said: I agree with Dr. Packard as to the pathological nature of the growth, and the possibility which he mentions is quite well recognized. An interesting feature of the case is the association of peritoneal effusion with solid growths in the abdomen. I have on several occasions been asked to see cases of ascites which depended upon the presence of tumors of ovaries or uterus.

Periscope.

Lacerated Wound of Brain.

At the meeting of the Medical Society of London, Oct. 22, 1888, Dr. Fletcher Beach read the notes of a case in which a boy was injured on July 20 by a window-pole being pushed into the cranium, 2¼ inches above and 1 inch to the left of the occipital protuberance, penetrating to the depth of an inch. There was some rise of temperature, with bad temper, and even delirium. The pulse too remained high, and on August 16 a cerebral abscess broke through the wound, and a quantity of greenish pus escaped. The patient was enabled to leave the hospital well on September 5. The treatment, apart from local antiseptics, was confined to tincture of opium, chloral, and bromide of sodium. Mr. Knowsley Thornton quoted a case related to him by Dr. Image, of Bury St. Edmunds. A boy, 7 years old, was struck by a sort of pitchfork, the prong of which entered the cranial cavity, carrying with it a quantity of filth. No treatment was adopted beyond the application of some carbolic lotion, but the lad made a perfect recovery. He suggested that children recovered from such injuries more easily than adults. Dr. Symes Thompson agreed with the remark as to the recovery of children, and mentioned that a month ago he saw a case brought before a medical society at Capetown in which Dr. Beck had trephined for suspected abscess of the brain. He, however, only alighted on the abscess after plunging the trocar three times for two inches into the brain substance. A good recovery resulted. Dr. Beevor asked if the sight had been affected in Dr. Fletcher's case. He recollected the case of a boy, who had been kicked by a horse on the head, but recovered. Dr. Money asked if any relationship had been found to exist

between the hernia cerebri and the frequency of the pulse. Dr. Fletcher Beach, in reply, said that he did not know of any symptoms having occurred subsequently. There were no visual troubles.—*British Med. Journal*, Oct. 27, 1888.

Inoculation of Syphilis by Tattooing.

At the meeting of the South-East Hants Medical Society, Oct. 11, 1888, Surgeon F. R. Barker read a paper on syphilis communicated by tattooing. The patients, three of whom were exhibited, were all soldiers of a regiment stationed at Portsmouth, and they were all tattooed by the same man, a discharged soldier. They were tattooed at various dates during the present year, and the periods of incubation varied from eighty-seven to thirteen days. In the first case admitted, the lesion appeared like a poisoned wound; but, two days after, two more men of the same regiment appeared with similar ulcers with hardened bases, caused by tattooing. The next day another patient was admitted with three inflamed patches on the arm, presenting well-marked rupial crusts. The fifth case was admitted a few days after the others, and from this patient a clue was obtained to the man who had performed the tattooing. This man was asked to come to the hospital, where he stated that he had tattooed about fifteen men of the regiment since its arrival at Portsmouth in April last. He at first denied, but aferward admitted, that he mixed his paints with his saliva, and wetted his finger and applied it to the part tattooed: he had also put the needles into his mouth. He used four ordinary needles on a piece of stick, quite as close together as he could get them. He used vermilion and India ink. He had never had a sore on his penis, but had had gonorrhœa. Whilst talking to him, Dr. Barker noticed a slight sore at the left angle of his mouth, and, on looking into it, the greater part of the buccal mucous membrane and soft palate was found studded with mucous tubercles. There was a coppery rash on his chest. On the glans penis there was a dark-colored scar the size of a shilling. This, the man said, had come a year before; he had had no treatment for it, and it went away of its own accord. He had also condylomata about the anus, and suffered from alopecia. The inguinal and cervical glands were enlarged. Of the fifteen men he had tattooed, eleven contracted the disease. Dr. Ward Cousins remarked upon the very unusual appearance of well-marked rupial crusts at the points of inoculation. He had never seen rupial prominences before, except during the secondary or tertiary stages of the disease. There was no previous history of syphilis in this case. All the patients were most certainly inoculated from the same source, and yet they presented very different forms of local inflammation and widely different skin disease.—*British Med. Journal*, Oct. 27, 1888.

Anthrax in Swine.

The *Lancet*, Nov. 3, 1888, says: Since among veterinarians some difference of opinion exists as to whether or not swine are capable of suffering from anthrax, or if cases described as anthrax may not be instances of septic poisoning, Professor Crookshank, at the request of Professor Brown, of the Agricultural Department of the Privy Council, carried out some experiments to ascertain the nature of the disease induced in swine by the ingestion of the offal of animals that have died of anthrax. He communicated his results to the Glasgow meeting of the British Medical Association. Professor Crookshank proved that the disease produced in swine by experimentally feeding them with anthrax offal was anthrax, which could also be produced in swine by injection of the blood of a bullock which died of anthrax, or transmitted to swine by injection of the blood of the spleen of a guinea-pig inoculated with the disease; and, lastly, produced in swine by direct injection of a pure cultivation of the anthrax bacillus. He was enabled to isolate the anthrax bacillus from cases occurring in the practice of Mr. Wilson of Berkhampstead, and concludes that anthrax can be communicated to swine, both young and old. A yellowish jelly-like œdema of the subcutaneous areolar tissue extends from the point of entrance of the virus, and, if the "disease is induced by ingestion of anthrax offal, the tonsils are found to be ulcerated, and constitute the point of access of the bacilli to the blood. In such cases the characteristic symptom is enormous swelling around the throat." The anthrax bacilli are very scantily present in the blood, due probably to the septic organisms which may readily have gained entrance at the same time from the offal consumed. As the anthrax bacillus rapidly disappears in presence of putrefactive organisms, failure to produce anthrax by inoculating guinea-pigs or mice from swine during an outbreak must not, if septicæmia is present, be held as conclusive against the outbreak being anthrax.

P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

AN ACCUSATION AGAINST PHYSICIANS.

Our attention has been called by a subscriber in Wisconsin to an item, said to be going the rounds of the Western papers, and copied from the New York *Herald*, which attributes to a clergyman in New Brunswick, N. J., the following language: "Judging from statements I have heard there are five hundred infantile murders committed in this city by physicians every year. The people need to be taught not only that this destruction of life is contrary to nature, ruinous to health and the cause of disease, but that it is murder and a sin against God. There are physicians who, knowing the penalty of the law upon those who thus destroy life, use their knowledge to make whatever demand they choose upon the guilty parties. The married women are said to be as bad in this respect as the unmarried." After this, the clergyman in question is said to have read a letter from the superintendent of the Florence Mission, in New York—an institution intended for the reclaiming of fallen women. The letter stated that the majority of the inmates, by their own confession, were first corrupted and influenced to lead a life of shame by their family physicians.

The item from which we copy these charges states that they had created a profound sensation; and our correspondent asks us to call the clergyman who made them to account. Before doing this we thought it proper to give him an opportunity to explain himself; and so we addressed him a letter, enclosing the slip and asking him if he had any comment to make on it. This brought a prompt reply, which is published in our Correspondence columns. This reply shows that the report in the *Herald* was incorrect, and did injustice to the clergyman as well as to physicians.

In considering the whole matter we think the Rev. Mr. McDuffie might have made a little clearer—if he did not—the distinction between the few physicians who practice criminal abortion and the great mass who regard this as a heinous crime. And we think he might have made a more guarded use of the accusation, coming from prostitutes, against family physicians. All who are familiar with the characteristics of such women as find shelter in the Florence Mission know that they not rarely seek to screen themselves behind the basest accusations of others. The Florence Mission itself has furnished a charge reflecting as severely against the clergy as the one above quoted against family physicians. Both charges may have some small foundation in fact; but neither deserves any consideration,

as bearing upon the reputation of the classes accused.

Physicians, so far from deserving such criticism as the Rev. Mr. McDuffie was reported to have made, are, as a rule, remarkably pure in the face of temptations such as surround no other set of men in the world. It is for this very reason that they enjoy the implicit confidence of maids and matrons, of husbands and fathers all over the world, and nowhere more than in the United States.

THE YELLOW FEVER PANIC.

More than once last year have we in these columns expressed our sympathy with those who, in various parts of the United States, have raised a voice against the unreasonable panic created by the recent outbreak of yellow fever at Jacksonville, Florida. Some of the events connected with the epidemic have suggested nothing so much as the ignorance and superstition of the Middle Ages. For the belief in horrible spiritual agents we have had substituted a belief in a germ endowed by the imagination with almost equally mysterious and improbable powers; and methods of combating it have been adopted which, in some respects, were as senseless as ever were practised. The worst of it all has been that some of these senseless practices had the real or apparent sanction of men who were chosen to direct the means of limiting the spread of the epidemic.

In a recently issued pamphlet by Dr. J. C. LeHardy, of Savannah, Georgia, entitled "The Yellow Fever Panic," there is a vigorous argument against the opinion that yellow fever is a contagious disease, and against the absurd methods adopted to prevent its spread, and the general neglect of efforts to prevent its outbreak.

Dr LeHardy has had a large experience with yellow fever, having lived through the epidemics of 1854, 1858, and 1876, besides attending numbers of cases in the intervening years. Dr. LeHardy attributes the production of yellow fever to a germ, but believes that the germ requires certain conditions of extreme heat and of moisture in order that it shall produce an epidemic. He points out the inefficiency of quarantine and the value of local sanitary measures to prevent the conditions which favor endemics of the disease, and especially condemns the way in which the authority delegated to the Surgeon-General of the Marine Hospital service has been used.

In the last received report of the Illinois State Board of Health, Dr. Rauch also protests vigorously against the ignorance and inhumanity brought to the surface in the recent epidemic, and especially against the senseless quarantine methods adopted.

In this we think he and Dr. LeHardy are entirely right. We have been anxiously hoping that this epidemic would furnish some valuable addition to our knowledge of the nature of yellow fever and the best method of preventing its outbreak and spread; but so far we have seen nothing of the kind—unless it be such protests as we have cited. It seems as if the learned and conclusive studies of yellow fever by Bache and others had been forgotten or ignored by those who have been dealing with the last epidemic, and we have little expectation of improvement until the health authorities return to the point reached by careful observers fifty years ago.

TRIBUTE TO DR. LEIDY.

The Philadelphia *Ledger*, Dec. 15, 1888, says: "Dr. Joseph Leidy, President of the Academy of Natural Sciences and Professor of Anatomy at the University of Pennsylvania, has had another honor added to the many he has had conferred upon him. A recent letter from the distinguished French naturalist, Milne Edwards, brings the information that the Cuvier prize of the French Academy of Sciences has been unanimously voted to him. The letter goes on to state that this prize has never been conferred except to the most distinguished scientists,

such as Agassiz, Owen, von Baer and Ehrenburg. The award is therefore all the more a great distinction. Dr. Leidy, though he receives honors from the ends of the earth, may have the gratification to know that his learning is nowhere more highly prized than in his native city, where those who know him best honor him most."

The Nation, December 20, 1888, says: "It will be gratifying to students of science in this country to know that the Cuvier Prize of the French Academy of Sciences, which is awarded triennially for the most important researches in the domain of general natural history and geology, and which has associated with it, among others, the names of Von Baer, Ehrenberg, Richard Owen, Agassiz, and Heer, has been this year decreed to the distinguished president of the Academy of Natural Sciences of Philadelphia, Professor Joseph Leidy. Following closely upon the award to the same scientist of the Lyell Medal of the Geological Society of London, and of the Walker Grand Prize of the Boston Society of Natural History, this recognition is a just tribute to the worth of one who has, with a degree of modesty uncommon to men of such eminence, kept himself well in the background among aspirants for fame and honors. There are probably few among the distinguished naturalists of this country who are less generally known than Professor Leidy, yet it is safe to say that during the last quarter of a century he has had no peer among the native-born, nor any co-laborer whose works have been held in higher repute by the savants of both Europe and America. As a comparative anatomist and microscopist, he easily leads the field; and if in the department of vertebrate palæontology he has seen rivals grow about him, it can yet be said that Dr. Leidy was the founder of the science in this country, and that to his pen belong the records of the first important researches made into the extinct life of the Western Territories. To Dr. Leidy, likewise, humanity is indebted in great part for the determination of the nature of trichina."

To these appreciative notices of the honor done to Dr. Leidy little can be added, except that those who know him best know that they are sincere and just.

NOT CRUELTY, BUT NOT SPORT.

The eminent physiologists to be found in all the petit juries in Queens County, New York, have now for the second time decided that rabbit coursing is not cruel. Certain persons, judging solely by appearances and guided by unreasonable prejudice, had assumed that rabbits suffered in mind and body when taken out, given a short start, and made to run for their lives from a pack of dogs. But Mr. August Belmont, Jr., and other like-minded sportsmen, maintained the contrary, and two juries of Queens County have supported them, intimating that rabbits rather like this kind of diversion, and that it would be a pity to interfere with their enjoyment. Unfortunately, however, for the prospective pleasure of the rabbits, the authorities of the Jersey City Kennel Club have announced that rabbit coursing, as carried out in this country, should be condemned by all true sportsmen, as it is condemned in England, where only people of low degree ever indulge in it. It seems too bad that the bright expectations of the rabbits should be thus dashed to the ground; but their friends will be pleased to learn that their existence will not be wholly monotonous; for they still have the excitements of the physiological laboratories left them, where very lately certain French investigators have subjected them to violent and prolonged shakings and other commotions, in order to get at the philosophy of sea-sickness.

—While heating a platinum point at a lamp, in the Cincinnati Hospital, Dec. 13, the lamp exploded and Dr. Hoppe was dangerously burned. The clothes of the patient on whom the doctor was to have operated caught fire and he ran out of the room.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

MEDICAL DIAGNOSIS. A MANUAL OF CLINICAL METHODS. By J. Graham Brown, M.D., F.R.C.P. Edinburgh, etc. Second edition, illustrated. 8vo, pp. 285. New York: E. B. Treat, 1888. Price, $2.75.

Dr. Brown's treatise on Medical Diagnosis is well and favorably known; but this particular edition has not much to commend it to professional esteem. If it is not an example of what is often called literary piracy, there is nothing in the book to correct the suspicion that it is. As a piece of book-making, it is what may be called pretentious. The paper is stiff and bulky, and the binding is showy but unsubstantial. The printing is very fair; but the illustrations are poor, and so few as scarcely to justify the use of the word "illustrated" on the title-page.

A MANUAL OF DIETETICS FOR PHYSICIANS, MOTHERS AND NURSES. By W. B. Pritchard, M.D. 8vo, pp. 88. Published by the Dietetic Publishing Co., New York. Price, 50 cents.

This little book contains a great deal of useful information in regard to the care of infants and invalids, and especially in regard to their food. The author considers first the care and feeding of infants, and then passes on to discuss the feeding of invalids in a variety of diseases. His views are in the main correct, and are founded partly on his own experience and partly on the writings of well-known medical men. A noticeable feature of the book is its enthusiastic praise of a certain food preparation. This is so enthusiastic as to excite suspicion; although the suspicion may do the author injustice. Be this as it may, the book before us has much to recommend it to the attention of medical men, and its moderate price places it within easy reach of all of them.

THE LIFE INSURANCE EXAMINER. A PRACTICAL TREATISE UPON MEDICAL EXAMINATIONS FOR LIFE INSURANCE. By Charles F. Stillman, M.S., M.D., Etc. Large 8vo, pp. 188 and appendix. New York: The Spectator Co., 1888.

The title of the book indicates the class of medical men for whom it is especially intended; but the volume contains much of great interest and value for all studious physicians. The opinions which guide insurance companies in accepting or rejecting applications for life insurance represent quite accurately the mature opinion of careful students as to the conditions which conduce to life and health or to death or disease. These opinions are, of course, valuable in other relations; and the careful reader of the book before us will find much in it which bears upon questions arising constantly in his professional relations with his patients. Matters of local and racial hygiene are discussed here with an acuteness sharpened by commercial interests of great importance; and the laws which restrain or protect life insurance companies are touched upon in a way which would interest everyone who wishes to be insured or who is concerned in the insurance of others.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

169. Acute Infectious Pharyngitis. By E. M. Hewish, M.D., Philadelphia. From the *Medical News*, Sept. 8, 1888. 5 pages.

170. Xeroderma Pigmentosum. By Buchanan Klophel, M.D., Memphis, Tenn. From the New York *Medical Record*, June 2, 1888. 8 pages.

171. Occurrence of the Mammary Secretion Accompanied by Certain Rational Signs of Pregnancy in Two Non-Pregnant Women. By George Woodruff Johnston, M.D., Washington, D. C. From the *American Journal of Obstetrics*, August, 1888. 6 pages.

172. Contributions to Abdominal Surgery. By Roswell Park, M.D., Buffalo, N. Y. From the *Medical Press of Western New York*, August, 1888. 7 pages.

169. Dr. Hewish gives the history of a curious case marked by inflammation and swelling of the soft parts surrounding the fauces, and afterward by diffuse swelling of the neck. In spite of the treatment, which included laryngotomy, the patient died on the ninth day of the disease. The history of this case is followed by a brief sketch of the pathology of the disease.

170. Dr. Klophel, who says he has never seen a case of xeroderma pigmentosum, gives in this pamphlet his views as to the pathology of the disorder, and recommends treating it with ignipuncture, using for this purpose the galvano-cautery.

171. Dr. Johnston gives an account of observations made upon two non-pregnant women who presented the phenomena of a milky secretion in the breasts, and sensations like those experienced by many women when pregnant. The cases are well described, and a brief study of the cause of the condition follows.

172. Dr. Park reports two cases: one a gastrostomy on a woman 47 years old, with stricture of the œsophagus, done under cocaine anæsthesia; the other a successful resection of the intestine for the relief of a fecal fistula.

The latter of these operations was of exceptional interest, and proved perfectly successful. Both are valuable contributions to the literature of abdominal surgery. The report would be better if the writer did not speak of operations being "made," and if he gave linear measures in English instead of in metric terms.

Literary Notes.

—The publisher of *The Writer*, Boston, Mass., announces the intended appearance of a companion periodical, to be called *The Author*, which will be issued on the fifteenth of each month, at one dollar a year, and contains original and selected matter of interest to literary workers. In calling attention to this publication, it is pleasant to be able to say that, if it is at all what the excellent character of *The Writer* would lead one to expect, we would be glad to know that every subscriber to the Reporter was also a subscriber to both these periodicals.

CORRESPONDENCE.

A Clergyman's Charges Against Physicians.

TO THE EDITOR.

Sir: Your note, inclosing me a slip cut from some newspaper referring to the *Herald's* report of a sermon preached by me in September last, has been received, and I thank you for your request and the opportunity which you give me to do justice to the medical profession and to myself by correcting the false statements made in the *Herald.* I attempted to correct the mistake by promptly writing to the *Herald,* denying the truthfulness of the report and specifying the points wherein it terribly exaggerated and perverted the statements which I made; but my letter to the *Herald* was never published, though duly received. It is very often utterly impossible to get some newspapers to correct the false reports which they make, without going to law: this I never do. I will try to give you in a few words the truth of the whole matter.

(1) I did not say that the infantile murders were committed *by the physicians* as a general thing, though they sometimes give the drugs and use the instruments for this purpose. On the authority of four of the most reputable physicians of this city I stated that the sin named was and is shamefully common in this city, and making a rough estimate I supposed that from three hundred to five hundred natural births were prevented every year in this city of 20,000 people. I am still of this opinion; and the further I investigate, by conversation with physicians and druggists and by reading medical books, the more I am convinced of the fact that this is "a great American sin." As for the physicians of this city, I distinctly stated that they would compare favorably with the other physicians of the United States both as to intelligence and moral character. I am still of this opinion notwithstanding the fact that I know some of them whose record is not clean. My remarks were not confined to the physicians of this city. I happened at the time to know of some disreputable work which was being arranged for by physicians outside of this city, and it was in connection with an effort to defeat wicked plans that I came into a knowledge of the terrible crimes constantly being committed here and elsewhere. You may rest assured of the fact that I did not make a false alarm. I knew what I was talking about and have seen no reason to change my mind.

(2) I read no letter from the Florence Mission in New York, nor did I pretend to read any such letter. I read a letter from a brother minister who gave me some facts to the effect that many of the fallen women who have been reclaimed by that mission attributed their ruin to their family physicians.

I did all I could to strengthen the hands and multiply the legitimate practice of worthy men, and all I could to warn my people against immoral physicians. In this I believe I have the sympathy and prayers of the best men in the medical profession. I have a higher respect and more tender feeling for men in this profession than for the men of any other profession, and I would not for any consideration injure their position in the estimation of the world. The man who reported for the *Herald* did not hear the sermon or read it, but got his points from others and fixed up his article so as to create a sensation, not realizing or intending to do the mischief which resulted. I feel that I am the most injured of all by the report, but freely forgive the reporter, as he did it ignorantly. Good will doubtless come of it. Sin needs to be exposed, and even if the enormity of it should by accident be exaggerated it is better than if nothing had been said. Please publish this statement and do me the kindness to send me a printed copy.

Yours truly,

M. V. MCDUFFIE,

Pastor Remsen Avenue Baptist Church, New Brunswick, N. J., December 17, 1888.

Velpeau's Compound.

TO THE EDITOR.

Sir: In answer to question 3 of Dr. G. M. Foskett (MED. AND SURG. REPORTER, Dec. 22, 1888, p. 789) allow me to inform you of Velpeau's formulas.

℞ Camphoræ,
Potassii nitratis . . . . . āā 5 parts
Pulv. radicis ipecac. . . . . 2.5 "
M. ft. pilulæ No. L.
Sig. One pill every three hours.

This is used in delirious states after operations, also in erysipelas of the face.

℞ Aceti rosæ . . . . . f℥ss
Aquæ destillat. . . . . f℥xx
M. Sig. For injection.

This is used in cases of granulations of the neck of the uterus, and also in leucorrhœa.

Yours truly,

B. SEGNITZ, M.D.

149 East 63d St., New York, Dec. 22, 1888.

Notes and Comments.

Amputation of the Pregnant Uterus.

Mr. Lawson Tait, in a paper published in the *Sacramento Med. Times*, Dec., 1888, says: This operation, I venture to predict, will revolutionize the obstetric art, and in two years we shall hear no more of craniotomy and eviscerations, for this new method will save more lives than these proceedings do, and it is far easier of performance. It is the easiest operation in abdominal surgery, and every country practitioner ought to be able and always prepared to perform it. No special instruments are required—nothing but a knife, some artery forceps, a piece of rubber drainage tube, two or three knitting-needles, and a little perchloride of iron.

My method of operating is to make an incision through the middle line large enough to admit my hand, and then I pass a piece of rubber drainage-tube (without any holes in it) as a loop over the fundus uteri, and bring it down so as to encircle the cervix, taking care that it does not include a loop of intestine. I then make a single hitch and draw it tight around the cervix, so as completely to stop the circulation. I give the ends of the tube to an assistant, who keeps them well on the strain, so as to prevent the loose knot from slipping; the reason for this being that should there be any bleeding and any necessity for further constriction, I could secure this in a moment, without undoing any knot; the simplicity of this method greatly commends it. I then make a small opening in the uterus, and enlarge it by tearing with my two forefingers, seize the child by a foot and remove it. I then remove the placenta, and by that time the uterus has completely contracted and is easily drawn through the wound in the abdominal wall. The constricting tube will now probably require to be tightened, and the second hitch of the knot may be put on at the same time, and the work is practically done. Stuff a few sponges into the wound to keep the cavity clear of blood, and pass the knitting-needles through the flattened tube and through the cervix, and in this simple way a clamp of the most efficient kind is at once made; the uterus is removed about three-quarters of an inch above the rubber tube. The usual stitches are put in, the wound closed around the stump, which, of course, is brought to the lower part of the opening, and then the stump is dressed with perchloride of iron in the usual way.

The operation takes far less time to perform than it takes to describe, and as there is hardly any possibility of complications; it is one of the simplest operations that can be undertaken, and must always be pretty much the same; for this reason no one need be in any fear about undertaking it; for, in the absence of variation in the difficulties to be encountered, it differs entirely from any other operation in abdominal surgery. If performed before the patient has been mauled about by ineffectual attempts to deliver, its mortality will be no greater than that of ovariotomy, and the arguments in its favor against all alternative proceedings are: first, that it cannot be more dangerous to the mother than most of these are; that it saves the life of the child; that it prevents the unfortunate mother from again being placed in a similar condition; and it certainly has the great advantage over alternative proceedings having a similar object, that its great simplicity, as contrasted, for instance, with operations proposed by Thomas, Müller and Sänger, will make it possible for the country doctor, less experienced in surgery, to perform it without hesitation. These complicated and difficult proceedings may have their advantages, though I confess I do not see them, but they will be left for the hands of experienced specialists. The operation I have described will be the operation of emergency, when only the resources of general practice are at hand.

Is the Communication of Infection an Assault?

A remarkable judgment was delivered last week by the High Court of Justice in London upon the question whether it is an assault in law to communicate an infective disease to another person. Thirteen judges considered the case, and it was discussed in all its bearings in the course of the delivery of the judgments. The prisoner was charged, under the Offences against the Person Act, 24 and 25 Vict., cap. 100, on two counts, with inflicting grievous bodily harm upon his wife, and with an assault, he having communicated to her a disease (syphilis). He was convicted, but the question of whether he could be properly convicted under the statute was reserved for the consideration of this Court. Mr. Justice Wills was of opinion that the conviction should be quashed. No mention was made in the statute of this class

of offences, and the alteration of the criminal law involved, if the conviction were affirmed, would have very widespread consequences. It was clear that what the Act contemplated was personal violence. Justices Smith, Mathew, and Grantham also were in favor of the conviction being quashed. Mr. Justice Stephen said that if the principle involved in a conviction was right, it must apply to women as well as men, and unmarried women as well as wives, and to diseases of any kind communicated by one person to another, and a man who had scarlet fever and shook hands with another might be indicted under these sections. He did not think there was grievous bodily harm or an assault of the nature contemplated by the statute. He was, therefore, of opinion that the conviction should be quashed. Mr. Justice Hawkins did not think the consequences shadowed forth by his learned brothers would follow if the conviction were upheld, and he could not be a party to a judgment which would proclaim to the world that, under the law of England, in the year 1888, a man might maliciously be guilty of such barbarity and not be punished. He thought the conviction should be confirmed. Mr. Justice Day, who was absent, concurred, it was said, in this judgment. Mr. Justice Manisty, Mr. Baron Huddleston, and Mr. Baron Pollock were in favor of quashing the conviction; while Mr. Justice Field thought it should be affirmed, as did also Mr. Justice Charles, who was absent. There being nine judges in favor of quashing the conviction, and four only supporting it, the conviction was quashed, in accordance with the view of the majority. Conviction quashed accordingly.—*Medical Press and Circular*, Nov. 21, 1888.

Creasote in Phthisis.

In a paper on Creasote in Phthisis, contributed to the *N. Y. Med. Journal*, Dec. 8, 1888, Dr. Austin Flint reports ten cases and says that the records of the ten cases reported show that creasote by the stomach and the inhalations (consisting of equal parts creasote, alcohol and spirit of chloroform) in cases of solidification without cavities, effect prompt and decided improvement in all phthisical symptoms, with increase in appetite, weight, and strength, even with surroundings much less favorable than would obtain in many cases in private practice. In cases with small cavities much less improvement is to be looked for, but some benefit may be expected. In cases with large cavities the treatment seems to have little more than a palliative influence. His recorded observations, he says, are defective as regards the influence of the treatment upon the bacilli. In one case, with large cavities, it was noted that the number of bacilli was diminished. No other examinations for bacilli were made during or after treatment.

No estimate was made of the relative value of creasote taken into the stomach. As regards the inhalations, it is assumed that the chief benefit was derived from the creasote, the spirit of chloroform and the alcohol rendering this agent more volatile, and soothing the mucous surfaces. The inhaled vapor undoubtedly penetrated by diffusion as far as the air-cells. It is by diffusion that fresh air, anæsthetic vapors, etc., penetrate the lungs, and cases of pneumonokoniosis illustrate the fact that even solid particles may be carried to the pulmonary vesicles.

Dr. Flint says he has employed the method of inhalation here described, conjoined with other treatment, in private practice, with good results. In a case of irritative cough of several months' standing, with slight bronchitis and emphysema, but no signs of phthisis, which resisted ordinary treatment, three inhalations produced complete relief, and the cough had not reappeared at the end of four weeks.

Fatal Error of a Druggist.

It is reported from Jersey City, N. J., under date of December 27, that a boy four years old had died as the result of having administered to him a medicine intended for another person. A prescription given for the boy was taken to a drug-store and left to be compounded. About that time another prescription was sent to the drug-store with the same instructions as to its being delivered. The two prescriptions were of a widely different nature, one of them being highly poisonous.

White Caps Attack a Physician.

A dispatch from Martin's Ferry, Ohio, dated Dec. 27, 1888, says: At Hopedale, Harrison County, Christmas night, White Caps visited Dr. John Parkhill, a leading physician, and gave him a terrible thrashing. His errand-boy had been intoxicated, and the White Caps accused Parkhill of drugging him.

NEWS.

—Dr. Frederick A. Packard has removed to 259 South Fifteenth Street.

—Prof. Unverricht has accepted the Chair of Internal Medicine in the University of Dorpat.

—The Annual Reunion and Banquet of the Ex-Residents of the Pennsylvania Hospital was held Dec. 27, 1888.

—Dr. Carl Zeiss, of Jena, who is widely known as the maker of the Zeiss microscopes, has just died at the age of seventy-three years.

—Prof. Billroth has been elected President of the Imperial-Royal Society of Physicians of Vienna, in place of the late Prof. von Bamberger.

—The Montfiore Home for Chronic Invalids was opened in New York City Dec. 18. There are accommodations in it for 180 patients. It is non-sectarian.

—At an address delivered in Edinburgh recently by Sir Morell Mackenzie, the more prominent members of the medical profession in Edinburgh were conspicuous by their absence.

—Contagious diseases still prevail to a considerable extent in New York City. During the week ending Dec. 22, there were 241 cases of scarlet fever and 53 deaths; 374 cases of measles and 24 deaths; 144 cases of diphtheria and 49 deaths.

—Dr. Charles W. Drew, in a communication to the *Norwestern Lancet*, Dec., 1888, on food adulteration in the State of Minnesota, states that of 1084 samples of foodstuffs examined by him, 470 were found to be adulterated and 614 of good quality.

—Dr. George Homan, Medical Examiner of the St. Louis Police Department, states that the police of that city are peculiarly liable to pulmonary diseases. Experience justifies the expectation that about half of all who join the St. Louis police force and serve ten years will die of consumption soon after reaching forty years of age.

A New Diathesis.—Dr. W. V. Morgan, of this city, recently attended a case of obstetrics in which there occurred *post-partum* hemorrhage. The nurse, who has picked up a few medical terms though her association with physicians, very innocently inquired of the doctor if he did not think the patient had a *hemorrhoidal diathesis.—Indiana Medical Journal.*

HUMOR.

Mrs. J. Browne Stone (who has just returned from Europe, to her daughter, who has staid at home)—"Good gracious, Emma! We must do something at once for your figure; it's getting as bad as the Venus of Milo's!"—*Puck.*

When to Imbibe.—Scene: Pharmacy in rural district. Enter typical "son of toil" hurriedly. Peasant: "Och, dochter, is it pizen oi've taken? Thry! Thry!" Chemist (smelling bottle): "Begor, Pat! it smells strongly of potheen." Pat: "Bedad, mebee it's meself brought yez the wrong cruiskeen." Gives it back. Then, pocketing the bottle, "Shure, Father Burke sez oi mustn't take any spirits, barrin' what I get frum the dochter, and amn't I doin' his biddin' entoirely? Top iv the mornin' t'ye, dochter, an' thank ye koindly."—*Chemist and Druggist.*

A Wide Distinction, Mind You.—Young physician (at a consultation)—"I have no hesitation in pronouncing the disease angina pectoris, complicated with muscular atrophy." Old physician—"You haven't, hey? Young man, when you have been practising forty years, you will have learned how to hesitate, sir. It is important, in a case of this kind, sir, to hesitate, and it is also more professional, sir." Young physician—"May I ask you, sir, what your opinion is of the disease?" Old physician (impressively)—"The disease, sir, is muscular atrophy, complicated with angina pectoris." Young physician (humbly)—"Yes, sir."—*Chicago Tribune.*

OBITUARY.

JOSEPH L. BODINE, M.D.

Dr. Joseph L. Bodine, a well-known physician of Trenton, N. J., died Jan. 2, after an illness of nearly nine weeks. He was about forty-nine years of age. His father, the late Daniel B. Bodine, was Clerk in Chancery from 1851 to 1856, and about ten years ago Mayor of Trenton.

Dr. Bodine was a graduate of Princeton College, and in 1865 was graduated in medicine from the University of Pennsylvania. He subsequently served as resident physician at the Episcopal Hospital, Philadelphia. He was for a time a member of the State Sinking Fund Commission, and ex-Governor Abbett urged him to retain the office, owing to his conspicuous honesty and ability, but the Doctor's professional duties compelled him to insist upon the acceptance of his resignation.

"NORTH CAPE"

Norwegian COD LIVER OIL.

IN STONE BOTTLES, Pints and Quarts.

This Oil is very carefully made from the finest fresh livers, and from the time of its production is kept totally excluded from LIGHT—a course that has been proved necessary to retain the entire medicinal value of the Oil.

On this account it will be found infinitely superior in palatability and digestibility, and in all cases where its use is indicated, positive benefit quickly follows its administration.

COD LIVER OIL DETERIORATES RAPIDLY WHEN EXPOSED TO LIGHT. THE "NORTH CAPE" IS CAREFULLY PROTECTED FROM LIGHT, AND WILL REMAIN FRESH AND SWEET INDEFINITELY.

To avoid confusion and to insure satisfaction, be particular to specify "NORTH CAPE" Cod Liver Oil.

Imported by **JOHN C. BAKER & CO.,** 815 Filbert Street, PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

LECTURE.[1]

FOODS FOR THE SICK.

BY MRS. S. T. RORER,

PRINCIPAL OF THE PHILADELPHIA COOKING SCHOOL.

(Specially reported for the MEDICAL AND SURGICAL REPORTER.)

Milk is by far the most important food which we have to give to the sick, as it contains all the substances necessary for the support of the human body. No doubt many of the recipes which I shall speak of are well known; still those who attempt to follow them often fail from lack of attention to small details; so I would emphasize the importance of following the directions which I shall give implicitly, and especially of being sure to measure each ingredient used.

A doctor will rarely be called upon to make these articles; but it is of the greatest importance for him to know exactly how to direct the person in attendance to prepare the food, and when prepared to be able to tell that it is made as desired. Where there is only one sick person to be provided for, it is wise to prepare small quantities of any food at one time, and in serving to be sure to have the food either hot or cold, and never lukewarm. When prepared, the same food should be presented at different times in different dishes, and uneaten food should never be allowed to remain in the sight of the patient.

Barley water.—Barley water is best prepared by taking one ounce of barley and covering it with one quart of boiling water; it is then to be boiled rapidly five minutes, and the water thrown away, as it has an objectionable color. Add a first boiled water—by this I mean water which has just come to the boiling point, and not that which has been drawn from the hot water faucet, or that which has been boiling on the fire for hours at a time. A first boiled water is cold water which has been heated

[1] Delivered at the University of Pennsylvania, November 21, 1888, and provided through the liberality of Dr. George Strawbridge.

rapidly until it boils and has not parted with its gases. Let the pot in which the barley and water have been placed simmer, not boil, gently two hours, strain, and it is ready for use.

Two thirds of milk and one third of barley water prepared in the above manner, make a most acceptable food, especially in typhoid fever, where we desire some starchy food.

Koumiss.—For koumiss mixed milk is the best, Alderney milk being too rich. Put one quart of sweet milk into a farina boiler, and stir constantly (over the fire?) until it has reached blood heat. Dissolve one quarter of a cake of compressed yeast in two tablespoonfuls of lukewarm water; stir the yeast until it is thoroughly dissolved. If you are unable to procure compressed yeast, two tablespoonfuls of liquid yeast may be used. Take one ounce of sugar (which is equal to two tablespoonfuls of sugar level to the brim) and dissolve it in two tablespoonfuls of water; stir over the fire until it boils, and then allow it to boil ten seconds; when you should have a perfectly clear syrup. Put the yeast into the milk and then add the syrup, stirring backward and forward, until they are thoroughly mixed.

Fill a quart bottle up to the neck with the mixture, and put in a tight fitting cork, which must be fastened down by means of a string; and keep the bottle in an upright position at a temperature of 70° F. for twelve hours; then in a temperature of 55° F., the bottle being placed on its side. The koumiss is ready for use in twenty-four hours; but patients often prefer it after standing forty-eight hours, as the taste is then slightly more acid.

Scalded milk.—There is a great difference between scalded and boiled milk. If we place milk in a farina boiler, no matter how hard we may boil the water underneath, the milk in the upper kettle will only be raised to a temperature of about 204° F., and this is not enough to boil milk. Scalded milk is often much more acceptable to a patient and not nearly as constipating as ordinary boiled milk. Put a quart of milk in a farina boiler and as soon as a scum of coagulated albumen floats on the surface the milk is scalded. In boiling milk the caseine which sinks to the bottom is apt to be burnt. I have known patients, who would become disgusted with boiled milk in a few days, to relish milk prepared in this way for months at a time.

Carrageen.—Take two pieces of Irish moss, thoroughly cleaned from any adherent sand and dirt, add some cold water, and let them soak five minutes; then wash, and allow to soak five minutes more in cold water, when the moss will have a soft, white look, and, having absorbed water, will be considerably increased in size. Scald one half pint of milk, and, after shaking any adherent water from the moss, drop it into the farina boiler. Stir well, and then cook, with the lid on the pot, for five minutes. Add one ounce of sugar. No flavoring extract is to be added unless especially ordered; but vanilla, wine, etc., may be added, or a sauce may be made and added to the jelly when cold. Strain through a sieve, and put into small moulds, which have been washed with cold water so as to prevent the jelly from adhering to the sides; then it is taken from the moulds and placed immediately on ice, or in a very cool place, and it will be ready for use in about one hour. It must be served very cold, or it will have a fishy taste. The quicker it is made, the better it is.

Milk punch.—Milk punch is made by taking two thirds of a tumbler full of milk and one half-ounce of sugar, and adding the amount of spirits ordered. The whole must be thoroughly shaken, with or without ice, in a wide mouthed bottle or a tin shaker; and then served in a clean tumbler. A little nutmeg grated on the top, makes the flavor more acceptable to some palates.

Egg-nog.—Egg-nog may be prepared with the whole egg, or with the yolk, or the white of the egg alone. If the whole egg is to be used, separate the white from the yolk and beat the white until it is light—not to so dry a froth, that it would stand alone. Then beat the yolk, and slowly add one half-cup of milk to it; put in some ice—not cracked too fine; add the white of the egg and one half an ounce of sugar, and beat until well mixed. Then add whiskey or brandy in quantities required, mix again, and serve at once.

If the white alone be used, mix as if making milk punch, but add from one to one-half ounce sherry, as this removes the taste of the white of the egg better than brandy or whiskey. Shake the whole as for milk punch. If correctly made there will be but little froth, the whole being of a light consistency. If the yolk alone be used, beat the yolk and add the milk slowly, beating all the time. Then add the sugar, ice, and spirits; and shake well.

Milk gruel.—Scald one half-pint of milk; add six good-sized raisins; and

allow to stand five minutes. Take a tablespoonful of corn-starch and thoroughly mix with two tablespoonfuls of cold milk. Add this mixture to the scalded milk quickly, stirring backward and forward over the fire in a farina boiler, until it begins to thicken; then add one ounce of sugar, and let it cook one minute. Strain, and place in moulds in a cool place.

Beef-tea.—Great care must be used in the selecting of meat for beef-tea, and that part of the meat is to be used which contains the greatest amount of nourishment. The piece best adapted for this is the "sticking-piece" (that part of the neck where the knife is thrust through in killing the animal), as here there is the greatest amount of blood in the part. The worst piece is the tenderloin. If the sticking-piece cannot be obtained, take the round. It is indifferent whether you use the upper part, which is the tender part, or the under side.

Take one pound of meat which has been well freed from fat, and chop it as fine as possible; add one pint of *cold* water; stir well; and allow to stand in a cool place for two hours. The cold water is added to soften the fibres and extract the juices. If boiling water is added a film is coagulated on the outside, and no amount of boiling will make it tender or extract all the juices. Stir the beef-tea, as it is soaking, every little while. Put in a farina boiler; but do not let it boil. For seasoning, it is better to add six whole peppers than the ordinary ground pepper. A bay-leaf imparts an agreeable flavor, and may often be added with no harm to the patient. Salt is to be added just before taking from the fire, because if it be added sooner the fibres are hardened and the juices are prevented from coming out. The fat that rises to the surface is to be removed with small pieces of white blotting paper. Keep stirring till the red color is changed to a slight white tinge, which will occur in about fifteen minutes. Then cover the kettle for a few moments and strain, pressing hard to get all the juices out.

It is wise to prepare beef-tea fresh every day, and never to hurry its preparation. Beef-tea is to be served icy cold or very hot; and to prevent the tea from cooling in being carried from the fire to the sickroom, it is wise to serve it in a metal tea pot, pouring the beef-tea into a cup only when the room is reached. Never warm up more than you intend to use, and any quantity left over must not be poured back into the remainder of the tea. The fibrin settles to the bottom, therefore before re-warming, be sure that the vessel in which the beef-tea is kept, is well shaken. When properly prepared, beef-tea should not have a cooked taste, like a soup, but should taste more like rare meat.

Clarified Beef-tea.—Take the shell of one egg and crush it in small pieces; add the white and a little water and beat until well mixed. Allow the beef-tea, prepared in the manner stated above, to come to a boil, and then add the shell and white of the egg. Allow the mixture to boil in a covered vessel for two minutes; and strain, and the dark colored beef-tea has given place to a clear light straw-colored liquid. This liquid is very stimulating and should not be given in more than two ounce doses at a time, or it may lead to dangerous symptoms from over stimulation.

Mutton Broth.—Mutton is less nutritious than beef, but is more easily digested, and can often be given when the latter should not be introduced into the system. The sticking-piece is the best part to use. Take one and one-half pounds of meat and one and one-half pints of water, and two tablespoonfuls of previously washed rice (if necessary the rice may be omitted) put on a slow fire, and allow to come to the boiling point; then remove any fat that may come to the surface, and allow to simmer for three hours. Keep the pan covered so as to prevent the evaporation of the water; strain; and re-warm as needed. Celery salt can often be added, and this imparts a nice flavor. The milky color is due to the rice.

Chicken Stock.—The legs and wing of the chicken make the best stock, as the sinews and bone in them contain gelatinous materials. The breast of the same fowl can often be saved and cooked for the patient in some other way. Take a one-pound chicken, which has been cut in large pieces and the bones cracked, and one pint of water, and allow it to soak three-quarters of an hour. Then simmer in a closed pot for two hours. Salt and pepper are then to be added, and the whole strained, and removed at once to a cold place. The fat is to be removed when cold, by a spoon. The solid stock as thus prepared can be used for food, or by adding water and heating, and afterward cooling, it may be served as a drink, or it may be given warm, in the form of soup, with or without rice.

Wine Whey.—The caseine can be removed from milk by acids, such as lemon juice, tamarind juice, wine, etc. Take one half-pint of milk; raise it just to the boiling point; add one-half as much sherry or madeira;

and remove it from the fire. Strain through a fine sieve or several thicknesses of cheese cloth. Do not squeeze, as all the curd must be removed—otherwise, it would be more indigestible than plain milk. Wine whey must not have too white a color, as this is a sign that the milk has boiled. Serve warm or cold, slightly seasoned.

Beef-tea with Yolk of an Egg.—Take one gill of clarified beef-tea, scalding hot, and thoroughly mix the yolk of an egg with a small amount of the liquid; pour quickly back into the pot; stir; and serve at once.

Cream Beef-tea.—One of the nicest and most nutritious dishes for the sick that I know of is prepared as follows: To one ounce of well made beef-tea, add an equal volume of barley-water; then heat, but do not boil the mixture. Add the whole to a half ounce of cream or to the yolk of one egg, stirring well. Heat for a minute, and serve at once.

Boiled Eggs.—To boil eggs so that they can be most easily digested, bring some water to the boiling point, drop the eggs in, and remove the vessel from the fire. Allow to stand five minutes, and when served the whites will be found cooked, but as soft as the yolk.

Scraped Beef.—Prepare two ounces of scraped beef by scraping a piece of beef in the direction of the fibres, and not across them. Put on a piece of bread one inch square, being sure that the meat is well pressed into the pores of the bread. Dust with salt, and toast both sides for a minute over a hot fire.

COMMUNICATIONS.

IDENTITY OF SCARLATINA AND DIPHTHERIA.

BY I. N. TRENT, M.D.,
COLUMBUS, O.

A few years ago the medical journals were teeming with arguments for and against the identity of diphtheria and croup. While the argument in favor of this doctrine seemed inconclusive to me, I wondered at the silence of the profession on the present subject. And while I wondered and waited the arguments and evidence kept piling up till the conclusion was irresistible.

The fact that they have so long been considered two diseases is no reason why the truth of it should not be questioned. Error may exist for centuries and when it is detected it is hard for us to believe we could have been deceived so long. For example, Galen taught that the blood passed directly from the right side to the left side of the heart through the pits he observed between the columnæ carnæ, which pits he supposed were the openings of foramina. This idea no one dared deny and "it stood undisputed for a thousand years and three centuries more." How strange it seems to us now that such a glaring error could be undetected under the eye of the medical profession for those thirteen hundred years.

Diphtheria meaning "a skin or membrane" is named from its gross pathological lesion. *Scarlatina*—"a deep red," is named from its prominent symptom. But these names signify nothing, for we have diseases named from the progress they make, as *cancer* referring to the movements of an animal; or from the actions of a patient as *chorea*—"a dance," and so on with no rule for the names we use. This is wrong and no doubt in time will be so changed that from the name of a disease its pathological lesion may be known. But what's in a name? "A rose by any other name would smell as sweet."

Thus, with no rule to guide in the application of names, it is not strange that one disease should receive two or more names as different observers were impressed by different pathological lesions, or different conditions, or symptoms.

So with the two diseases under consideration; one is named as we have seen from its pathological lesion, the other from its prominent symptom; but this difference of name does not prove that the diseases are *two*.

If, on the other hand, it can be shown that they are alike in etiology, pathology, symptoms and sequelæ, and then cases cited where one disease is generated from exposure to the other, it must be conceded that their identity is highly probable.

This I shall attempt to do by a careful research of the literature of the subject, and by the report of a few cases from the records of a private country practice, where every facility is present for knowing the source of infection. And what we have to say as to pathology, cause, symptoms, or sequela, is substantiated by these works and again by the cases recorded.

As to *Pathology*.—Both are infectious. Both are but slightly contagious. Both are diseases of the glandular structure, affecting regularly the adenoid tissue; the adenitis being a part of the disease and not a complication. Both present a croupous inflammation of the mucous membrane of the

tonsils and pharynx, often extending to that of the stomach and bowels. And, according to Drs. Delafield and Prudden, "such a croupous inflammation in diphtheria is anatomically identical with croupous inflammation due to trauma and *other* causes."

Admitting then on their authority that the throat trouble is the same, it behooves us to show that the causes are the same. This we can not do, but far less can it be proved that they are different. And as to their etiology, we know nothing positive of their real cause, but judging from its effects and mode of behavior, it is generally conceded to be a micro-organism. The micro-organism of these diseases has not yet been subjected to the crucial tests of always finding it present in the lesion, of isolating it by a series of pure cultures, and, lastly, of reproducing the disease by inoculation with these isolated cultures. Prof. Palmer says: "The specific character of diphtheria, its dependence on a poison, cannot be doubted. But the positive character of that poison has not been demonstrated, and its mode of action in producing such serious results is unknown." The same may be said of scarlatina. While acknowledging the want of knowledge as to the exact germ, we must all have been impressed by the similarity of its workings in the two diseases.

In both it acts best, or the susceptibility is greatest, between the ages of two and seven years. In both the period of incubation varies from a few hours to seven or eight days, with an average of four days. In both the micro-organism clings to life with great tenacity, each disease having been contracted by persons occupying rooms where many months before there had been patients affected by one or the other disease. In both it is often impossible to trace the source of infection. Hence we say both are sporadic, if not spontaneous. In both the contagium not only is carried directly from the sick to the well, but it may also be communicated through a third party, or through fomites in which it may lie dormant but preserve its vitality. Both attack and complicate wounds. In both one attack produces immunity against future attacks as a rule, while recurrent attacks in either are not very infrequent.

In symptoms both vary from the mildest to the most malignant type. Both have a common seat of croupous inflammation, namely, the mucous membrane of the fauces and nasal passages. Both agree in the profound toxæmia and prostration in graver cases. In both there is an eruption.

In *sequelæ* they agree by both having the adenitis and nephritis, which are considered as a regular part of the disease, but which some consider as complications. J. Solis Cohen calls especial attention to the physical resemblance between the pseudo-membranous casts in diphtheria and the desquamated epidermis of scarlatina. In both we have paralysis of the muscles of the throat.

Now, having shown these striking similarities as conceded by the authors quoted above, I present a few cases in which most of the points of identity are illustrated. I well know I am likely to meet the thought, whether expressed or not, that I have been mistaken in my diagnosis, and that the cases I called diphtheria were simply scarlatina without the eruption.

While I claim to have ordinary observing powers, and to be capable of making a differential diagnosis, as it is generally called, I must fortify my position by stating that every case but one was seen by one or two other good practitioners of many years' standing, practitioners whose opinions stand unquestioned where they are known.

Case I.—Myrtle H.—After complaining a few hours the patient was seized with a general convulsion. I saw her in half an hour and found her in a state of great prostration, with the twitching of muscles and the rolling of the eye-balls so characteristic of approaching convulsions Her temperature was 104°, which steadily increased to 106½° just before death, which occurred in twenty-four hours from the time of first convulsion. When she was first seen there was a croupous membrane on both the tonsils and on the posterior wall of pharynx. At this time considerable swelling of the glands of the neck was present, which steadily increased. An eruption was to be seen, dim but sufficiently distinct, when taken with the other symptoms, to warrant a diagnosis of scarlatina. a diagnosis which was confirmed by Dr. Clarke, who saw her shortly before her death.

No history of contagion nor of infection could be obtained; her two brothers and her sister did not take the disease, though they were in the room during her sickness.

No other case occurred for 10 days, when I was called to see

Case II, Bert W., 12 years old, who lived three miles from the first patient. I saw the patient on the second day of his sickness, and was informed that a diagnosis of diphtheria had been made the day before by another physician. The throat did look

like it, but a further examination revealed a typical scarlatinal eruption on the body and limbs. The case ran a favorable course, ending in profuse desquamation followed by general œdema. The only source of infection was association with the man who held Case I in his arms while the patient was in her first convulsion, ten days before.

Case III.—In five days after Bert was attacked, Worden K., who was living in the family with Bert, was stricken down and had a typical case of scarlet fever.

Case IV.—Mrs. W., the mother of Bert, in a week from the beginning of the latter's sickness was attacked by fever and sore throat, with a deposit on both tonsils and pharynx, and every symptom to make a case of diphtheria. No eruption was present at any time.

Case V.—Clint W., the brother of Bert, in two weeks after the latter's illness was attacked by chill, vomiting, fever, and all premonitory symptoms of scarlatina, which subsequently developed.

Case VI.—Lanie W. was a playmate of Bert whom Lanie had visited a week before he was attacked, and while Bert was in the midst of his fever. When first seen he had a temperature of 102½°, and a typical diphtheritic deposit in the throat. No eruption was then to be seen, nor did any appear afterward. He was said to have had scarlatina nine years before.

Case VII.—In five days after Lanie was taken sick his sister, Bessie W., was taken with a chill, and in eighteen hours was thoroughly covered with a scarlatinous eruption, with a diffuse mottled redness of the throat, but no deposit. In due time desquamation came on and the muscles of the throat were partly paralyzed for several months, to such a degree that she swallowed with difficulty, and articulation was at first impossible. Both gradually improved.

Case VIII.—Charles R., a neighbor to W.'s family, where Bert, Clint, and others lived, did not himself come in contact with the sick, but from the beginning of sickness in this family his wife visited them often. In eight days from the beginning of Bert's attack this patient was stricken down with what I pronounced diphtheria, a diagnosis confirmed by Dr. Clarke.

The next group of patients was three miles distant from the first group just reported, and had no communication with them whatever.

Case I.—While visiting Myrtle (Case I of the first group) a messenger came hurriedly saying that his child had croup. I had seen the patient, Opal W., two days before, at which time she had a temperature of 100°, with a slight deposit confined to the tonsils. At that time she had a dull, listless expression, which I was informed had existed for a week. Knowing this much about the case I at once concluded the croup was due to extension downward of the false membrane I had seen two days before. Upon visiting her I found her very hoarse, with a pseudomembrane covering both tonsils, the pharynx, and extending high up on the soft palate and as low down as I could see. I at once made a diagnosis of diphtheria, with a fatal prognosis. Dr. Franks saw her with me in the evening of the same day, and confirmed the diagnosis. At this evening visit the hoarseness was nearly gone, but in no other respect was she better. Next morning her temperature was 104°, and she was fast sinking. Diarrhœa had set in during the night. Fluids regurgitated through the nostrils when she attempted to swallow, showing paralysis of the muscles of the throat.

The source of infection in this case could not be found, but may be conjectured as follows: The patient and Myrtle—the first patient of the first group—had been taken to a large funeral three weeks before. As both were attacked about the same time, and as this had been the only place at which either had been from home, it seems probable that both were infected at this funeral, though one died of scarlatina and the other of diphtheria.

Case II.—Five days after Opal died her brother, Claude, was seen with a characteristic diphtheritic deposit in the throat, and all the symptoms which go to make up a case of diphtheria. No eruption appeared and he made a good recovery.

Case III.—The night before Opal died, Mrs. C. attended her, holding her in her lap. Without changing her clothes she went home among her own children. In a week Ed. C. was attacked. In twenty-four hours he was thoroughly covered with the eruption of scarlet fever, which ran a severe course, but ended in recovery after an abscess had formed on each side of the neck.

Case IV.—A week after Ed. was attacked his sister Alma was attacked with a sore throat which looked like that of diphtheria; no eruption was ever seen.

In another family consisting of father, mother, and five children, the five children had well-marked scarlet fever, while the mother had as severe and as well-marked an

attack of diphtheria as I ever saw recovered from. The false membrane covered the tonsils and pharynx and extended up over the soft palate and out on the hard palate to near the incisor teeth. She was exposed to no infection except from her children with scarlet fever.

This family had no communication with either group of patients reported above.

In addition to my own cases, I offer a few from Dr. Mendenhall, of Woodford Co , Ill. He says: "A young man who had been West came home sick. I saw him the day after his arrival and found him suffering with diphtheria. He had been boarding in a family in which one child had died of this disease. This young man recovered, and his sister, two years younger, was then attacked with diphtheria and had a very hard struggle with the disease. Before she recovered her two younger sisters, five and seven years old respectively, were attacked with scarlatina, the younger one dying. There had been neither scarlatina nor diphtheria in the neighborhood up to that time. Immediately afterward I treated in that neighborhood four cases of scarlatina and nine of diphtheria. The original case was one of diphtheria, and the first two patients with scarlatina were in the house with it. Undoubtedly the scarlatina was developed from contagion of diphtheria."

Dr. J. B. Clarke, of Economy, Ind., to whom I referred as seeing some of my patients, writes: "I am quite willing to be quoted as confirming your diagnosis in the cases to which you refer. I have observed for many years the close relation between diphtheria and scarlatina, and believe them to be identical. A number of times when scarlatina was prevailing epidemically, I have had in the same family well-marked cases of scarlatina and of diphtheria. I have never known an epidemic of scarlatina without quite a good deal of diphtheria in the same locality. I have no doubt of the identity of the two diseases."

In the transactions of the Chicago Medical Society, Nov. 16, 1885, I find the following: Dr. Carter mentions the fact that simple cases of tonsillitis are often accompanied or followed by diphtheria or scarlatina among other members of the same family. Dr. Quine says: "Often one member of a family, probably the first one attacked, exhibits plainly-marked features of simple follicular tonsillitis, and those who sicken afterward exhibit the phenomena of diphtheria or, less frequently, those of scarlatina."

Dr. Stevenson relates a case in which a child took scarlatina from its mother who had tonsillitis. The child died and the Doctor says: "This is the first case in which I ever suspected that a benign form of tonsillitis might reproduce a malignant form."

Dr. Angear, at the same meeting, comes nearer advocating the doctrine of identity when he says: "We can readily imagine a robust, healthy child, with strong resistance to morbid influences, and especially that of diphtheria, on exposure would have simple tonsillitis; but suppose his brother, with strong susceptibility, is exposed to the same morbid influence; he will develop a case of undoubted diphtheria.

"In this house we have tonsillitis and our neighbor severe diphtheria. By remembering these facts, we shall see that it is, or may be, all the same morbid influence here and yonder—here, recovery in a few days; there, death in a few hours."

I have shown by the case of Bert that scarlatina may be conveyed by a third party from one with scarlatina; and by Charles R. that diphtheria was carried from scarlatina; and by Ed. C., that scarlatina may be carried from diphtheria.

From Bert, who had scarlatina, two cases of scarlatina and three of diphtheria developed; from Lanie, with diphtheria, his sister contracted scarlatina; from Opal, with diphtheria, her brother contracted diphtheria, and Ed. C., scarlatina; from Ed., his sister contracted diphtheria. Opal, with diphtheria, had paralysis of the muscles of the throat, which also occurred in the case of Bessie, sick with scarlatina.

Let me insist that when I say diphtheria I mean this dreaded disease, and not every affection of the throat in which there is an exudation; and that I rule out all cases of simple and follicular tonsillitis, which are so often classed as diphtheria by a class of practitioners who desire the reputation of curing all cases of diphtheria. Another thing I wish to emphasize is the inability to trace the source of infection in city patients, and the reliability of an investigation of this matter by a country practitioner. For parents in the country can tell every place to which the child has been for six months, and also who has been at the house, and almost everyone who has been within a mile of the patient for the same length of time.

Knowing this and having my diagnoses confirmed by such reputable physicians, and my ideas corroborated by such careful country practitioners as I have mentioned, and the, to me, unanswerable argument

presented by the cases recorded, I am forced to the conclusion that scarlatina and diphtheria are very, very similar, if not identical.

503 Oak Street.

TYPHOID FEVER.

BY J. A. LONG, M.D.,
LONG'S MILLS, TENN.

Since Feb. 4, 1888—the date of my short article on typhoid fever in the REPORTER—I have witnessed a remarkable endemic of typhoid fever, in Polk County, Tennessee. In seeing, diagnosticating, and treating fevers for more than forty years, I never met with so puzzling a group of symptoms before in my practice.

The fever district was about six miles long, by three wide — lying between the Hiwassee River (a tributary of the Tennessee) and Chilhowee Mountain, a part of the Allegheny range. This section of country is mainly level or slightly undulating, and interspersed with basins of water in wet seasons, like the latter part of the past summer and fall. The soil is poor and sandy, and is mainly drained by three small streams which take their rise at the base of the mountains, running a little south of west across the fever-stricken section, and emptying into the Hiwassee River. The streams are quite subject to overflow, spreading over a considerable amount of low lands, depositing a quantity of filth and mixed soils, in various portions of this particular section of country; in wet seasons this part of the country is mainly cultivated in cotton by renters, some of whom are colored people, nearly all of them living in old, dilapidated log-houses, with a great many small outhouses, in a filthy condition. Near the river there are some large, well-ventilated, and comfortable dwellings; in which also the fever prevailed to a considerable extent. The water supply comes mostly from shallow wells, not in the best condition.

The disease was confined to persons in the prime of life—none, I believe, under ten, or over thirty or thirty-five years of age. The onset of the disease was invariably slow, insidious, and tedious; the patients moped around for some days, or even weeks, before being confined to their beds, complaining of nothing but weakness, and indisposed to mental or physical exertion. One of the first symptoms worthy of note after the patients were confined to bed, was sick stomach and vomiting of bilious matter. This latter symptom, in some cases, was quite troublesome and intractable—fully as much so as in bilious remitting fever—and was accompanied with a bilious diarrhœa. The morning remissions were pretty well defined, and seemed to be controlled by the use of quinine; but this drug had little or no influence upon the regular course of the disease. The coat on the tongue would peel off, and again reappear, as in typical cases of typhoid fever. The tongue was not so pointed, nor its edges and tip so clean and red as is usual in typhoid fever. The pulse was quick and small, with a well-marked reacting beat, even when the patient was perspiring well from the use of quinine. It would range from 90 to 100 beats in a minute in mild cases, and from 100 to 120 in grave cases.

The range of temperature in all cases that came under my observation, was in proportion to the gravity of the case. The duration of the disease was from four to ten weeks in cases of recovery; and the fatal cases were from three to five weeks in duration.

Abdominal symptoms.—A tympanitic state of the bowels was not common, in the cases I saw; the bowels seemed flat, and rather hard, very sore on pressure, and especially if pressure was made over the right iliac region. The bowels had to be controlled throughout the entire course of the disease; the color of the evacuations was yellow, and dark, and they had a strong bilious odor. Epistaxis and hemorrhage from the bowels were seen in many cases. The latter symptom was probably induced in some of the cases by the use of too frequent, or strong purgatives, as there were several physicians in the fever-stricken district entertaining very different views of diagnosis and treatment.

The disease was diagnosticated, by the various practitioners who saw it, to be nearly every kind of fever known to the medical profession. I think most practitioners, seeing one of these cases early in its onset, would have been inclined to call the disease grave bilious remittent fever, and more especially if they ignored, or paid little or no attention to, the tediousness of the onset. The impression made upon my mind, in seeing the first case, was that I had a grave case of bilious remittent fever to contend with, strongly marked with a *typhoid type:* and I remained twenty-four hours with the patient watching the action of medicine, and left undecided as to the real nature of the case, and impatiently waited the further developing of symptoms.

On my next visit I saw plainly I had a case of typhoid fever in a person with a malarial diathesis—what some practitioners call "*typho-malarial fever.*"

I stated in an article on typhoid fever, published in the *Augusta Medical and Surgical Journal*, about the year 1854 or 1855, when the late lamented Dr. Eve was its Editor, that where typhoid fever prevailed, malarial fevers were uncommon, and *vice versâ;* and I have had no cause to change my opinion until the present endemic occurred. This is the first time I ever witnessed a typhoid fever endemic or epidemic, or even sporadic cases in a district in which malarial fevers were prevalent. Others I have no doubt have a different experience; especially in malarial districts of old settled countries. There can be little doubt that the poisons of malarial and typhoid fevers are as essentially different as are the poisons of small-pox and typhoid fever, or of any one of the specific diseases. I have examined as faithfully as I could, with the limited means at my command, into the cause or causes of typhoid fever; and in this section of country have certainly traced them to *filth;* such as is found in old, damp cellars, filthy drinking-water, cesspools, old filthy out-houses, and accumulated about old farm-houses and out-buildings. I could illustrate these facts by the recital of many cases. I think the facts are as well established as that so-called malaria produces periodical fevers. It is well known by all observing medical practitioners who have many years' experience, that the home of periodical fevers is in newly settled countries; and that of typhoid fever is in old settled places. This view of the subject does not limit malarial fevers to new settled districts or typhoid fever to old settled ones; but as a rule what I have stated is the case.

The belief that different kinds of microbes in malarial and typhoid fevers, develope different groups of symptoms and require altogether different medicines, as germicides, seems to have brought us no nearer to successful treatment in either form of fever; nor do I think it ever will. While I am willing to admit the fact, of the finding of different kinds of micro-organisms in the various diseases of the human body, I cannot believe that they are the cause of disease, but look upon them rather as its *product.*

My reason for diagnosticating the fever of this endemic as typhoid is this: that the remarkable group of symptoms which makes up the picture of typhoid fever was clearly seen throughout its entire course. Notwithstanding the sick stomach, the vomiting of bile, the bilious stools, the absence of tympanites in many cases, the fact that the tongue was not very characteristic, and that there were pretty well defined morning remissions in the fever apparently yielding to quinine, obscured the diagnosis. We had the tedious and insidious onset, bleeding from the bowels, epistaxis, constant diarrhœa throughout the entire course, soreness of the bowels, especially over the right iliac region, attended with a gurgling sound on pressure, a quick nervous reacting pulse, even when sweating was free; and the length of time in running its course even in those cases that progressed to a favorable termination. The muttering delirium so characteristic of typhoid fever was not well marked; the mind as a rule was clearer but slow and dull. This feature was so striking that I made it a practice to inquire after the natural turn of mind, and speech, when the patient was well.

I have said nothing about the *rose spots*, because I saw none of the patients before the end of the third week, and I found only what I took to be a faded eruption, but was not positive as to its existence.

I have but little to say on the subject of treatment, as I saw no patients but such as were far advanced in the disease—one of them, a negro girl, died from hemorrhage of the bowels. I saw one patient, who had been sick for seven weeks; who had had but little attention or treatment; she was treated in a mild conservative way with a proper course of diet, and stimulants, and she got up at the end of ten weeks. Others that I saw were slowly convalescing. I saw the last patient about November 30. I failed to meet the family physician, and, as the patient was doing well enough, I only advised following the directions given by his regular medical attendant, and that the patient should not be in too great a hurry about leaving his bed.

The fact that these attacks have extended into the winter months is confirmatory of the diagnosis of typhoid fever.

Finally, I would like to say that it seems to me we ought to have more help from our fellow-practitioners in regard to the matter of fevers, and less on gynecology. I cannot see why a practitioner is not entitled to as much credit for diagnosticating, and successfully treating a grave case of fever of any kind, as if he had performed a successful laparotomy.

JABORANDI.

BY J. B. CARRELL, M.D.,
HATBORO, PA.

In conversation with physicians, I find that the great value of this drug in the cure of disease is not fully appreciated, and for this reason I wish to speak of it.

The plant is found in Brazil, and its botanical name is *Pilocarpus pennatifolius*. The only alkaloid of value so far found in it is pilocarpine; others have been found, but they are of little use to the therapeutist.

As an introduction I shall state that the more the drug is employed the better it will be liked; at least such is my experience. The class of diseases in which it should be used is of the active or sthenic type, such as congestion of the lungs, pleura, and of other organs, in which are found great dryness of the skin and a high grade of fever. Its value in the early stages of high inflammatory conditions is very marked, and justly deserves a place in every physician's list of medicines. If an infusion of from sixty to ninety grains of jaborandi, or an equivalent of its active alkaloid, pilocarpine, be given to an adult, profuse perspiration will be produced in from thirty minutes to an hour, and will continue for several hours. The salivary glands will act quite freely, and if the saliva is swallowed, nausea and vomiting will in all probability be produced. This nausea, according to the observations of some, seems to be due to the irritating character of the saliva coming in contact with the stomach. Dr. Bruen, of Philadelphia, asserts that the dialysate of pilocarpine will not produce sickness of the stomach. The pulse and respiration are usually quickened and the temperature for a time may be slightly increased, but will soon begin to fall; at least it has done so in my experience. After the sweating has ceased, the patient is more or less exhausted, and should on no account be allowed to leave the bed unless he is well covered, in order to prevent chill and the syncope which may result therefrom.

The nasal and lachrymal secretions are very generally increased, and Gubler has noted diarrhœa. Ringer and other experimenters have not found this present. There is sometimes contraction of the pupils and even disturbance of vision. Ringer found children very insusceptible, but such has not been my experience either in children or in adults; the dose is not always constant, that is, free diaphoresis may be produced in one person with ten drops of the fluid extract given every hour, for three or four hours, while in another double this amount may be required, or even quadruple to produce the same effect. The sweat produced by jaborandi is often enormous in quantity. In cases of nephritis the loss by weight after injections of pilocarpine, according to Dr. Zelentski, of St. Petersburg, was 514 grammes or more than one pound; 306 grammes were lost by perspiration and 208 by salivation. The elimination of urea is said to be especially marked. For this reason the drug is valuable especially in destructive kidney diseases. The cause of the excessive secretion is a direct action upon either the gland-cells or the peripheral nerve endings, more probably the former. On account of its certain and powerful action as a diaphoretic it has taken rank as the most reliable remedy of its class, and has greatly extended the use of diaphoretics. It will be well now to take up its use in the various diseases.

In the early stages of pneumonia, that is, in the congestive stage—characterized by sudden rise of temperature, throbbing pulse, dryness of the skin, hurried and difficult respiration, chilliness, etc.—where my esteemed friend, Dr. Hiram Corson, would employ the lance and cold pack, I will, with equal confidence, put my patient to bed and produce free diaphoresis by the administration of jaborandi. With the appearance of free sweating there will be an amelioration of all the violent symptoms and a speedy and perfect cure within three or four days. A temperature of 105° in congestion of the lungs has, time and time again in my practice, been reduced to 99.5° in twenty-four hours.

While my friend, Dr. Corson, applies the lance to relieve the active congestion, I can produce as decided an effect with the drug under consideration. What has been said of congestion of the lungs can be said also of pleurisy. I am not writing from fancy but from experience.

Dr. J. M. Da Costa says that the pilocarpine treatment of erysipelas grows upon him, and, in thus speaking, my own views are expressed. It may be well to narrate one or two cases described by this eminent physician: "In a case of erysipelas of the face and leg the patient was given one-sixth of a grain of pilocarpine by hypodermic injection; two hours later he was given one-eighth of a grain and was purged with a mercurial pill. He was then ordered

twenty drops of the fluid extract of jaborandi every two hours, when he *did* sweat, and the disease was checked in twelve hours after the first hypodermic; the temperature went down to normal and he made a rapid convalescence from that time. He is now taking twenty drops of the fluid extract thrice daily; he still sweats, and his urine has increased from two and one-half to three and one-half pints in the twenty-four hours. The drug did not have sialogogue effects, nor did it seem to have any action on the heart. The second case is one of erysipelas of the nose. On admission the temperature was 103.5°. After the injection of pilocarpine it fell to 100°, later to 99°, and has never since been up to the fever temperature."

A week ago I was called to see a young man with erysipelas of the hand and arm, which were much swollen and very hot and painful. The temperature was 104°, pulse 120, with chilliness and general febrile symptoms. I gave him twenty drops of fluid extract of jaborandi every hour and a half alternately with three drops of tincture of aconite and one-half drop of extract of ipecac. In twenty-four hours the temperature had fallen to 99.5°, and all the unpleasant symptoms had disappeared. Locally warm flaxseed poultices and laudanum were applied. The treatment was completed by giving five drops of tincture of iron and two drops of Fowler's solution three times daily. I could mention many similar cases, but they would make needless repetition. If there is a tendency to exhaustion it is well to combine nux vomica and digitalis as heart tonics. By this course exhaustion will be obviated and the good effects of the drug secured.

Jaborandi has been largely employed for the relief of dropsies, especially the dropsies resulting from the destruction of kidney substance. In uræmic poisoning it is the most efficient remedy at our command. It is certainly of great value in either acute or chronic Bright's disease. The œdematous collections formed in this disease can be relieved by the use of jaborandi. It is asserted confidently by some that it acts in a special manner upon the kidneys, helping to free the tubes when they are obstructed with epithelial or fibrous *débris*. In the acute cases, in conjunction with proper diet, it may bring about a cure. The word "cure," says a writer, should be used in this connection in the same sense in which we apply the word cure to any other disease in which organic changes have taken place; or, in other words, the cure would consist in assisting nature to stop a morbid process by throwing off effete material, and by placing a barrier between diseased and healthy structure. The principle upon which we base our action is the benefit to be derived from *rest* in the relief and cure of inflammations. By the use of jaborandi the skin performs double duty—its own work and also that of its co-laborer, the kidneys. The latter are rested and inflammatory action is suspended. Wherever and whenever we can, we should place inflamed tissue at rest. That which cannot be cured with medication may without medicine be cured by rest.

In scarlatina, jaborandi is a most valuable remedy. It can do valiant service. Its well-known action upon the skin makes it of especial use in all of the exanthematous diseases. I have used it in a great many cases of scarlatina with the happiest results, and cannot help thinking that many cases of nephritis might be obviated by its use.

Little has been said of the value of jaborandi as a galactagogue. The mammary glands in many respects resemble the action of sudoriferous glands, and in cases in which the milk supply has failed, or is failing, it can be increased and redeveloped by the administration of jaborandi. This has been conclusively proved by numerous experiments. To obtain the galactagogue effect jaborandi should not be given in sufficient doses to effect free diaphoresis. In case of scanty supply, daily doses are required for ten or twelve days If there is complete cessation of the milk secretion, it will be necessary to administer the drug every three or four hours, until gentle diaphoresis is established, and then keep up daily doses until the secretion is fully established. The patient, as is usually the case, will be run down, and should be built up with tonics and a generous diet. On January 5, 1885, I delivered a multipara of a fine boy baby. I saw her on the 6th, 7th, and 9th. At the last date the milk secretion was established and the temperature was normal. On the 11th, I was summoned and found her temperature 105°, pulse 130, severe headache, chilliness, coated tongue, dry burning skin; secretion of milk stopped, and breasts extremely sensitive and inflamed. The symptoms were as bad as one could wish if a test were needed for a drug-trial. I ordered free doses of jaborandi every two hours until free sweating had taken place. In three or four hours the dry hot skin was moist and in six hours she was in a dripping sweat. Small doses of quinine were given

every four hours and also five drop doses of extract of jaborandi. Twenty-four hours after the first dose of jaborandi the temperature had fallen to 99.5°, the milk was re-established and every unfavorable symptom had become favorable. This is one of several cases I have treated in this manner, and the result has been highly satisfactory.

The action of pilocarpine and atropine are directly antagonistic, so that in cases of belladonna poisoning jaborandi should be employed as the physiological antidote I have not had the opportunity of testing their antidotal effects, but others have had, and in the cases I have seen reported the results have been favorable.

Dr. H. C. Yarrow, of Washington, D. C., has been recently experimenting with the view of determining the value of certain reputed antidotes to serpent venom. All of them in his hands have thus far proved useless with the exception of the fluid extract of jaborandi, which seems to possess antidotal powers—at least in the case of mammals; but upon fowls it appears to have no such effect. He has given hypodermically to rabbits fourfold lethal doses of crotalus venom, and then by the administration of thirty-five drops of the fluid extract of jaborandi he has prevented any serious results. Dr. Josso, of Paris, reports a case of viper bite cured with an infusion of jaborandi leaves.

While much more could be written on the subject, I think what I have already said will awaken an interest in this very valuable drug, and am sure that its powers and uses will be appreciated if they are fully tested.

—Dr. Ira Russell, of Winchendon, Mass., died December 19, of pneumonia, at the age of 74 years. He was graduated from the Medical Department of the New York University in 1844.

—The Tennessee *State Board of Health Bulletin* for November, says: The number of localities reporting the existence of typhoid fever each month in Tennessee demands of the local health authorities immediate and careful investigation. No water or soil contamination, no typhoid fever, is the axiomatic teaching of sanitary science, and consequently no weary weeks of suffering and prostration, no long nights of anxious watching by friends, and no untimely deaths, whereas hundreds are now annually consigned to premature graves by this preventable scourge.

ODD COURSE OF A MISSILE.

BY E. H. PARKER, M.D.,
POUGHKEEPSIE, N. Y.

Very few persons practise surgery many years without meeting with instances in which missiles, such as bullets, pieces of shells and so on, take curious and often inexplicable courses after striking the bodies of living animals. In the following instance I was as much surprised as in any case with which I have met. In preparing for a frolic, a young man made a cannon by taking the long axle-box from the worn-out wheel of a horse-rake, plugging one end thoroughly, and boring a touch-hole. After loading this cannon, he fired it, and it being made of cast iron, and only one-fourth of an inch thick, it naturally blew to pieces. One of the fragments struck him. When I was called to see him, some thirteen hours later, it was evident that the missile was just underneath the skin of his neck, its upper end just touching the left mastoid process, and the only "solution of continuity" to be found was over the sternum, three-fourths of an inch below the upper end of that bone, and extending a little to the left of the median line. This wound was parallel to the upper margin of the sternum, was three-fourths of an inch long, and one-sixteenth of an inch wide. There was no discoloration of the skin at any point except that of entrance, which was a little bloody.

Making my preparations to meet any possible injury to the blood-vessels of the neck, I cut down upon, and removed, the fragment. Some bits of clothing were found just above the missile. There was no bleeding, and the patient recovered entirely in a few days.

The piece of iron weighs nearly two ounces (twenty-one grains short), is three inches long, one-fourth of an inch thick, and from three-fourths to seven-eighths of an inch on its convex surface for half its length, and then tapers to three-eighths of an inch. The other end, which was against the mastoid process, is broken almost square off, and is three-fourths of an inch across. All the edges of the fracture-lines are sharp and cutting. The convex surface of the fragment was next the skin. It has always puzzled me to understand how this piece of iron got through the small wound over the sternum, and from that point to the mastoid process, without breaking the clavicle and without doing any serious damage.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, December 24, 1888.

The President, Alexander S. Hunter, M.D., in the chair.

Dr. Ralph L. Parsons read the history of

A Case of Cerebral Syphilis,

more for the purpose, he said, of emphasizing the importance of early and long-continued anti-syphilitic treatment than because of special interest in the case itself. The man, forty-five years old, of good constitution, married, came under his care with symptoms of loss of appetite, sleeplessness, depressed physical and mental condition, worry about business affairs, and fear of softening of the brain. His friends attributed his condition to worry over the sickness of his children. He began to have attacks of impending fainting, during which his ideas became confused, and he had difficulty of expressing his ideas. Before the attacks he was irritable. In spite of anti-syphilitic treatment, under which he improved for a time, he became worse, had attacks first of *petit mal*, later of *grand mal*, and finally died of symptoms due to syphilis of the brain. There had been no history of impure connection. But before Dr. Parsons saw him there had been a suspicious intractable ulcer of the lip. There was also evidence of syphilis, in sores on the scalp and in an eruption on the arm. It seemed probable that the cerebral symptoms might have been averted by early and long continued treatment.

Dr. Nathan S. Roberts read a paper on the

Treatment of Diseases of the Nose by the General Practitioner,

in which he called attention to some of the more common affections of the nose which when neglected were of great local annoyance, and frequently gave rise to reflex conditions which could only be cured by treatment directed to the nose. Among these reflex conditions which have been well established by both European and American authorities are: asthma, hay fever, vertigo, headache, disturbances of vision and of hearing. It is not necessary that the general practitioner should devote as much time to special training as is required of the rhinologist in the treatment of nasal affections; but with a moderate amount of clinical experience at the dispensary or medical school he will readily learn to do minor operations, to use the nasal speculum and mirror, to make applications of astringents and caustics if necessary, and to resort to those cleansing measures which are of so marked benefit in catarrhal affections. Speaking of chronic nasal catarrh, he said it is not only liable to invade the Eustachian tube, but to extend and involve the larynx and pharynx. The constant flow from the nasal passages into the stomach is a source of much disturbance to that organ. If the same care and discrimination were bestowed on these cases as are commonly given, for instance, to uterine diseases, the result would be at least equally successful. The author dwelt somewhat on the liability to loss of smell and its attendant dangers from long continued nasal disease, and sometimes from wrong treatment, such as the use of too strong astringents, or of mild ones too long continued.

Dr. Egbert H. Grandin then read the principal paper of the evening, entitled

A Plea for the Active Treatment of Puerperal Endometritis by Means of the Curette.

The profession, he said, accepts novelties in many other branches of medicine with much less conservatism than in obstetrics. While it is desirable not to manifest undue haste in the acceptance of new things, lest it appear like meddlesome midwifery, yet the author thought we should not reject good things because they had not been practised by our forefathers. Every day adds to the knowledge of the obstetrician who carefully watches his cases, and sooner or later facts show him that his early training in some respects has been faulty, and he may attain to that stage when he will admit that judicious meddlesomeness is good.

After delivery, the interior of the womb resembles a large surgical wound, except that the condition is physiological and not the result of disease. During a physiological puerperium the vast degenerative and regenerative changes going on in the womb and genital tract take place without disturbance of health; but if the normal process is arrested the fatty metamorphosis becomes checked or is replaced by necrosis; the cellular elements, the thrombi, etc., take on so-called puerperal degeneration. This process may start from any point in the endometrium, but usually from the placental site, and it extends progressively until it involves the whole surface. The surface,

often extending down to the muscularis, becomes converted into a mass of pus cells and a vast cicatrix. A part of the degenerative material becomes absorbed into the circulatory fluid, and gives rise to constitutional symptoms. If the surgeon found such a condition after amputation of a limb he would get rid of the slough as soon as possible. He would not rest satisfied with simply washing the wound and sprinkling on iodoform. He would remove decaying matter with the forceps and seek to establish healthy granulations.

The theory of to-day is that puerperal endometritis or septicæmia is a septic process arising from the introduction of germs into the genital tract. Without stopping to inquire whether this theory is well established, Dr. Grandin said it served his purpose to state that in the vast majority of instances the septic process is localized at the outset. The cases which constitute exceptions are those to which the French have applied the term *septicæmie foudroyante*.

The necessity for attacking the septic process while it is local, and before the poison has thoroughly invaded the general system, becomes evident to all. The symptomatology gives a very early clew to puerperal endometritis, yet the obstetrician requires the use of all his senses. Before the pulse, or the general aspect of the patient or of the lochia indicates danger, the physician will frequently find reason for suspicion in the odor imparted to his finger on examination of the cervix.

Prophylactic measures are of the greatest importance. As far as possible, asepsis should be observed during the lying-in period. Dr. Grandin does not approve of the routine use of the intra-uterine douche after delivery. If the accoucheur has reason to believe a part of the placenta or membranes is left behind, he should remove it, otherwise there will be great risk of puerperal endometritis. If it is good practice to keep out germs, it is better practice to leave nothing in the uterus which will prove a fertile soil for their development. If, however, endometritis has developed, what shall we do?

The practice of to-day seems to be to use the intra-uterine douche. As a rule, the fluid now employed is a solution of bichloride of mercury in water, and the douching is repeated once in three hours by some, by others as often as once in two hours or every hour, and it is continued sometimes a full week. The object of the douche is to stop the septic process. There are objections to this method. That the douche is not always effectual, but that eventually an adjuvant has to be resorted to, is the experience of all. The difficulty, if not the impossibility, of douching decomposing shreds out of the uterus has been demonstrated by experiments in washing shreds out of a bag. Then the danger of the toxic effect, even of death, from the agent commonly employed has to be considered. In certain maternities in Europe this danger is thoroughly recognized, and the use of a solution of corrosive sublimate is prohibited. Dr. Grandin had not used it in the intra-uterine douche for two years. There is the further objection to this mode of treatment, that it is often repeated and causes disturbance of the patient. There is also some danger of re-introducing septic matter, when the injections are continued at intervals for days.

It is the author's belief that we possess in the dull curette an instrument which will often replace the douche and at the same time answer all the indications. The indications are: to remove from the uterus the products of decomposition, whether free in the cavity, partly adherent, limited to the superficies, or extending to the muscularis. Timely action is important, for at the outset the septic process is limited to the cavity of the organ. Soon it goes beyond local measures. The dull curette is harmless if used with care, as every instrument should be. The practitioner should be as competent to use it understandingly as to use the forceps or insert an irrigation tube.

The method which Dr. Grandin prefers to the repeated douche, and the value of which he has in a number of instances established to his own satisfaction, is the following: As soon as fetor of the lochia appears he proceeds carefully to differentiate its source, and without going into the details of the differential diagnosis it is sufficient to say that a thorough vaginal douching with boiled water or antiseptic solution will cause this fetor to disappear, in case it is due to decomposition in the vagina. If the fetor soon returns, also after the intra-uterine douche, it may be regarded as an indication for active treatment. He then places the patient in Sims's position, introduces the speculum, seizes the cervix with the tenaculum, inserts the curette, and thoroughly scrapes out the interior of the uterus. Finally he gives another douche, and then confidently expects to see a marked change for the better within twenty-four

hours. Thus will be accomplished at once by the curette all that the douche can do if continued days. He deprecates as much as anyone unnecessary interference with the genital tract after labor, but when the necessity arises he believes in speedy action. It will be observed that he does not advocate the radical measure until the milder ones have been tried and failed. The use of the dull curette is attended with no more danger than the use of the irrigation tube, but if anyone fears it, he may resort to Doléris's brush.

The paper was discussed by Drs. Janvrin, Currier, R. A. Murray, Jacobus, and others, who agreed in the main with the author.

PERISCOPE.

Pelvic Peritonitis.

In the *American Journal of Obstetrics*, September, 1888, Dr. Joseph Eastman states that from his experience in the past year he feels warranted in emphasizing the importance of pelvic peritonitis—a disease often overlooked, yet the most common disease of the female pelvis. According to the text-books, pelvic cellulitis more frequently follows labor than pelvic peritonitis. Post-mortem examinations, and, within the past few years, abdominal sections, are demonstrating that without some pre-existing peritonitis, the trauma of child-birth, and other causes heretofore related, would less frequently result in cellulitis. He refers to the autopsies (for all diseases) made by Winckel — well-marked pelvic peritonitis was found in one-third of the cases. The same authority found pronounced disease of the Fallopian tubes in 182 cases, out of a total of 575, which were examined *post-mortem*. These instructive statements should lead to the early medical treatment of salpingitis, which so frequently causes inflammation of structures contiguous to the tubes owing to their movements and periodical engorgement.

The sharp stitch-like pains felt by young women before, during and after menstruation are, as in the chest, significant of more or less inflammatory adhesion of some portions of the serous covering of the pelvic structure. The term pelvic peritonitis may be applied to a circumscribed spot of inflammation, or signify coexistence of perimetritis, perisalpingitis, perioöphoritis, pericystitis, and periproctitis. The delicate silky membrane at first becomes opaque, then adheres to the fold of peritoneum nearest in contact. Thus the uterus, rectum, tubes and bladder may become adherent one to the other, or all together: and each recurring attack of inflammation strengthens the adhesions. The serum poured out may become purulent, forming abscesses in the broad ligament, or between coils of intestines; these seriously impair various functions, sometimes causing intestinal obstruction. Should they discharge into the bowel or bladder the ultimate cure is seriously complicated.

Congenital defects in the sexual organs may favor the development of peritonitis. The brain-cramming of our school systems is also a predisposing cause, since it interferes with the normal development of the pelvic organs in young girls. Allusion is made to the observation of Tait that disease of the tubes is at times due to the exanthemata, which probably act by causing catarrh of the tubes, or by interfering with the proper development of the epithelial lining of these organs. Dr. Eastman has removed diseased tubes from several cases in which the history clearly showed that scarlet fever was the cause of the disease. While gonorrhœa is admitted to be a frequent cause of pelvic peritonitis, the extreme views of Noeggerath and Saenger are not accepted. Still there is reason to shudder at the fate of marriageable young ladies when it is remembered that a large percentage of marriageable young men have suffered from gonorrhœa, and have been imperfectly cured, or rather, not cured at all. The teaching, heretofore extant, that gonorrhœa in the female is less serious than in the male is wrong, *and must be rewritten*. The statement of Van Buren and Keyes that "gonorrhœa sends more to the tomb than syphilis" is quoted with commendation, and it is added that the same foul virus sends twice as many women to the grave as men. While serious lesions in the urethra (resulting from gonorrhœa) are less common in the female than in the male, the Fallopian tubes and ovaries furnish a secret lurking-place for the gonorrhœal virus, where its work of destruction is beyond the reach of remedial agents. Means used to prevent conception, especially cold water injections used after coition, cause many cases of tubal and ovarian inflammation. Induced abortion is a prolific cause of peritonitis from which many deaths result.

The treatment given refers more particularly to advanced stages of the disease, in which operative treatment alone offers a prospect of benefit or cure. Opium is still

accorded the first place in the treatment of acute peritonitis; but we are warned against its use in chronic cases, lest the "opium habit" be induced. Hot applications to the hypogastrium, combined with hot antiseptic vaginal douches, given with the Hildebrandt douche (which instrument allows the use of water ten or fifteen degrees hotter than can be borne by the external parts) are also regarded with favor.

In case that each recurring menstrual period rekindles the inflammation, removal of the uterine appendages, to relieve the pelvis of its periodical congestion, is undoubtedly a warrantable operation if all other methods of treatment have failed. [Are not the appendages removed as the *fons et origo mali* rather than to bring on the menopause, and when peritonitis is caused by pyo-salpinx is it not warrantable to remove the appendages before employing all other methods of treatment?—Ed.] In answer to the claim that the uterine appendages are being removed without sufficient cause, Eastman states that from his limited experience he believes that for every case in which these structures have been removed, unnecessarily, ten women have gone to the grave whose lives could have been saved by timely removal of the appendages by skilful hands.

The attention of those who condemn salpingo-oöphorectomy is called to the following propositions, and they are requested to use anatomical, physiological, pathological, and therapeutical common sense in the consideration. Could the ovaries and Fallopian tubes, like the testicle and epididymis, descend during early life and remain within reach of poultices, iodine, suspensory bandages, etc., and if they could remain free from monthly engorgement, they also might be relieved of congenital defects, physiological abuses, the destructive sequelæ of mumps, the fevers of childhood, and the pernicious gonorrhœa virus, before disorganization had so far advanced as to necessitate their removal. After suppuration has occurred, whether the pus is discharging by the rectum, vagina or not, the treatment instituted by Tait—to open the abdomen, drain the abscess from its fountain source (whether in the broad ligament or between coils of intestines) by stitching the peritoneal margins of the abscess to the abdominal wound and using the drainage tube—is considered the safest and most satisfactory method of treatment. It is preferred to opening the abscess *per vaginam* with the trocar or bistoury; also to enlarging sinuses communicating with the vagina and rectum when such exist. Martin's method of drainage through Douglas's pouch may be more suitable in some cases.

Rupture of the Quadriceps Extensor Femoris.

Dr. W. R. Cluness, in a letter to the *Sacramento Medical Times*, Nov., 1888, says: The subcutaneous rupture of muscles or tendons is a comparatively common occurrence, the rupture usually taking place at the junction of the muscular with the tendinous tissue. Erichsen says that it occurs more frequently from the muscular contraction, which must necessarily precede it, than from direct violence. Gross, Ashhurst, and indeed all of the authorities I have found it convenient to consult upon the subject, convey the idea that much force is always necessary to cause this kind of injury, especially when a muscle or tendon of considerable size becomes ruptured. The few cases that have heretofore come under my observation confirm this view, or indicate that sudden and unexpected tension is necessary, even when not accompanied by very great strain. When therefore the complete rupture of so powerful a muscle as the quadriceps femoris takes place during the ordinary efforts of walking, and without stepping upon a pebble or other similar substance, or in any manner encountering an obstruction which would in the slightest degree impede locomotion, it is deemed worthy of permanent record. The history of such a case is briefly as follows: G. W. D., 75 years old, 5 feet 8 inches in height, and weighing 188 pounds, a well-preserved and robust man, apparently ten years younger than he really is, and of good habits, while returning from a few hours' recreation at fishing in the Sacramento River on the 20th of last month, and while carrying a small string of fish in his left hand as he was slowly wending his way homeward, distinctly heard a snap, as if his thigh bone had been broken. Falling backward instantly, he endeavored to prevent himself from sustaining injury by quickly throwing his arms behind him for support, but so sudden and unexpected was the seizure that he fell to the earth before he could realize what had occurred. He says: "I first heard a crack, and away I went, heels over head, turning a complete somersault; I then flopped around on my face and tried to get up, but could not; I tried again and failed.

By this time I realized that my leg was paralyzed, and I called for the assistance of the Yard-Master of the S. P. Co., who soon placed me in a hack and sent me home." Upon reaching his home I was immediately summoned, and readily diagnosticated a rupture of the quadriceps femoris at its insertion into the patella, the separation being complete and the detached end being distinctly felt fully two inches above the upper border of that bone. Treatment for the first two weeks consisted in the relaxation of the ruptured muscle, by position, and the application of an evaporating lotion to subdue what inflammation might ensue. There having been but little pain at any time, no anodynes were required. He is now, just a month after the accident, able to move about in his room upon crutches, the limb being properly bandaged, and the joint rendered immovable by suitable appliances.

Resins used by the Ancient Egyptians.

A small jar of resin was recently submitted to Mr. E. M. Holmes for identification by Mr. Flinders Petrie, of the Egypt Exploration Exhibition. This jar, which was in a perfect state, was disinterred from a heap of rubbish found among the ruins of Naucratis and dates from the sixth century B.C. Naucratis was at this time the only Greek colony in Egypt, and it was through this town alone that trade with Greece was permitted. Mr. Holmes states in the *Pharmaceutical Journal* that the jar contained Chian turpentine. According to Flückiger there is no evidence that the old Egyptians were acquainted with the resin. The discovery of this pot of resin carries the history of the commerce of the drug two hundred years further back. The other resin was found on a mummy cloth on the body of a person to all appearance of some rank. It was found in Hawara Cemetery, in the Fayum province of Lower Egypt, and it dates from a period not earlier than the second century A.D. On heating some of the resin in a flame, the vapors of benzoic acid were given off, and a decided vanilla odor was recognized. This points to the conclusion that the resin must be a Siam benzoin. The authors of the Pharmacographia state that there is no evidence that the Greeks and Romans, or even the earlier Arabian physicians, had any acquaintance with benzoin.—*Lancet*, Nov. 24, 1888.

Value of Salicylic Acid in Dermatology.

At the meeting of the American Dermatological Association, at Washington, Sept. 18, 1888, Dr. C. Heitzman, of New York, read a paper on the value of salicylic acid in dermatology, in which he said that he had been using the remedy for the last three years. It has two well-marked properties. The first is the peculiarity of acting on the horny layers of the epidermis. There is no agent so active in softening, and at last destroying, the epidermal formations as salicylic acid. Its other action is as a parasiticide. These two properties open a large field for research. We should be careful not to include cases in which we have merely impressions as to its value; but there are many cases in which there can be no question as to its utility, and in some of these it has never been used before. The remedy may be used as a powder, as a plaster, or in the alcoholic solution. It has the advantages that it does not discolor the skin or linen, and has no odor. It is used in twenty-four kinds of cases. In hyperidrosis its action is well known. The German soldiers use it in a one per cent. salve, made with tallow, applied to the feet when upon the march. In seborrhœa, especially when combined with acne, it has given brilliant results. One per cent. of the acid with six to eight per cent. of sulphur, is an excellent application for dandruff. A prescription with tar Dr. Heitzman likes better, but it is less agreeable to the patients. In urticaria it is an excellent means of allaying the itching. In furunculosis an ointment of six to ten per cent. has prevented an outbreak and checked the disease. But, to be sure of results, the quality of the acid must be guaranteed. In two cases in which the prescription had been filled at random there had been no good result, but when Scheering's salicylic acid was substituted the effect was immediate.

In one case of dermatitis herpetiformis a lotion of the acid proved the best thing the patient had tried, although it was not capable of smothering the disease or preventing recurrences. In psoriasis, after chrysarobin and tar, it is the very thing to be applied, though the peeling off of the scales is not so rapid as with other remedies. In lichen planus salicylic acid is far superior to carbolic acid or corrosive sublimate. It can also be applied over a larger area with safety. It allays the itching, removes the scales, and flattens down the papules. The author has prescribed three per cent. solutions, which are to be diluted at the beginning of treat-

ment. Six cases were treated, and all did uniformly well without the administration of arsenic.

In all varieties of eczema the results were satisfactory. Ninety-six cases were treated, generally with one per cent. of the acid, with equal parts of zinc-powder and starch, in two parts of ointment. In eczema madidans, one-half per cent. is better. Sometimes it may be used as strong as ten per cent. where there is great thickening in the very chronic cases. As the acid does not attack the connective tissue, there can be no caustic effect. In acne a three per cent. solution removes pigment patches, assists in removing comedones, and renders the skin soft. In acne rosacea the results were good, but in sycosis less good. The remedy does not seem to penetrate deep enough between the furrows. In impetigo contagiosa it cures the disease in ten or twelve days. If combined with the liquor gutta-perchæ and some oil to make an emulsion, it adheres to the skin. In keratitis senilis, callosity, clavus, and verruca its action in removing the thickened portions is well known. In ichthyosis it is easy to remove the scales, but they return. In lupus erythematosus and lupus vulgaris the results were brilliant at first, the excrescences flattening down rapidly at first, but not a case was cured. For pruritus, in the shape of a lotion, it is excellent. In tinea the solution with gutta-percha is better than Taylor's remedy. But generally the disease will not be cured by any one remedy, and we are only too glad to have more than one. In tinea versicolor a one per cent. solution is effective.

Dr. Pye Smith, of London, spoke of his use of the remedy in the hypertrophic inflammations in the soles of the feet and the palms of the hands where there were fissures; here the effects of the remedy are wonderful. He corroborated what Dr. Heitzman said in reference to the use of the remedy in furunculosis, especially as it occurs in youths or school-boys, sometimes for months together. He believes that the contagion is carried from one point to another in the dressing. In the treatment of the individual pustules he always hardens the surrounding skin by bathing it in lead lotion, thus giving less opportunity for the invasion of the micro-organisms than does the old method of poulticing, which makes the skin sodden and readily permeable. In lichen planus he has tried the salicylic acid with some success, but has found it difficult to follow the cases closely enough to be sure of his ground. He prefers to wait till more material has been collected. In general, he said he felt that there were not enough cases to warrant definite conclusions.

Dr. L. D. Bulkley, of New York, said he had used the remedy largely in many of the cases referred to, and mentioned particularly hyperidrosis of the axilla in women. He uses with great confidence a ten per cent. powder, with one drachm of oxide of zinc and the rest starch. In eczema care must be used. He has seen acute attacks started up by it. He also mentioned favus of the scalp, in which he considers salicylic acid very valuable in the form of a strong lotion. He has had several cases under observation for several months, and the disease has not yet returned. It is good in seborrhœa, but, if it is too strong, even when mixed with oil, the patients come back and say it is too drying.

Dr. A. Van Harlingen, of Philadelphia, uses it in the treatment of chronic eczema of the legs in a paste with glycerine and zinc oxide, made into a paste with five per cent. of the acid. If it is carefully applied, the patients go for from three days to a week without redressing.

Dr. E. B. Bronson, of New York, thinks that in most cases we use the remedy as a preliminary measure, as it prepares the surface for other remedies. This is true especially where there is an enormous accumulation of the epidermis, as in cases of seborrhœa. In these cases he has generally been obliged to resort afterward to some other remedies.

Dr. Heitzman, in closing the discussion, said that the field of the remedy in hyperidrosis extends to any portion of the body which is affected, especially the folds of the groin and the genital regions.—*N. Y. Med. Journal*, Dec. 1, 1888.

Formula for Chronic Cystitis.

At the meeting of the Sacramento Society for Medical Improvement, Oct. 16, 1888 (*Sacramento Med. Times*, Dec., 1888), Dr. Mary J. Magill read a paper on the treatment of cystic disease in women, in the course of which she said that the following formula had proved very serviceable:

℞ Ol. cubebæ,
Ol. santali,
Ol. copaibæ . . . . . āā ʒiii
Liq. potassæ . . . . . ʒiss
Syr. acaciæ,
Aquæ anisi . . . . . āā ʒiiiss

M. Sig. Two teaspoonfuls every 4 hours.

Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

REGULATING VETERINARY MEDICINE.

A committee of well-known practitioners of veterinary medicine in Philadelphia and other parts of Pennsylvania has recently drawn up an address to the Legislature, recommending to its attention the importance of adopting some measure to regulate the practice of veterinary medicine in the State. The address recites the value of the cattle in Pennsylvania, which is put at about one hundred and twenty-five million dollars. In addition to this, the committee dwells upon the danger of communication of tuberculosis from animals to man.

In doing this they have fallen into an exaggeration which may do their cause harm. This is to be regretted, because their cause is a good one, and could be maintained on its merits. There can be no serious question of the importance of legal regulation of the practice of veterinary medicine, as all enlightened communities ought to regulate the practice of medicine among human beings.

At present a large part of the practice of veterinary medicine in this country is in the hands of uneducated and even ignorant men; and animals are often subjected to medication, and other treatment, which is barbarous and worse than useless. To remedy this condition of affairs, the State should use its influence and authority to compel those who wish to enter this calling to prepare themselves by study in some of the excellent schools to be found in this country or abroad; and it is plainly its duty to protect its citizens against the malpractice of those who have no right to assume the responsibilities of veterinary medicine.

With some modifications, the bill proposed by the Committee we have referred to would do a great deal to this end, and it would also furnish a much-needed stimulus to the study of veterinary medicine, by making the title of veterinary surgeon more honorable than it is now. There is, we believe, a great opportunity in this country for the ambition of first-rate men in the study of the nature and treatment of diseases of the lower animals. So far, few men of ability and promise in the United States have cared to devote themselves to this pursuit; but more will do so whenever it is understood that such a course opens up a most inviting field for scientific investigation and an excellent one for financial success.

The bill proposed will tend to elevate the standing of veterinarians in the community, and to encourage the kind of men to study veterinary medicine who are most needed in this department of science, for the good of the community and for the credit of their calling.

THE PROGNOSIS OF CARCINOMA AFTER OPERATION.

No one who is familiar with the recent advances in surgery can fail to appreciate the change which has taken place during the last ten or fifteen years in the attitude of surgeons toward the treatment of patients suffering with cancer. The time was, and not so long ago, when surgeons regarded the removal of a carcinoma as an operation involving great danger to the life of the patient, and as furnishing but a temporary and brief freedom from active manifestations of the disease. Nowadays the methods of wound treatment have been so perfected that the danger to life is reduced to a minimum, and it hardly enters into the calculation of results, except when the cancer occupies some peculiarly dangerous position.

The final result of an operation for cancer falls under one of three heads: first, perfect success, when a patient recovers from the operation and lives for years without any local or remote recurrence; second, partial success, when the patient recovers from the operation and lives for a period of months before recurrence takes place; and, third, failure, when the patient dies soon after the operation, or suffers with local or distant recurrence of the growth within a very short period.

In looking over the whole field, using statistics in a legitimate way, and giving due weight to what is of equal worth, namely, the opinions of skilful and experienced surgeons, it appears that the modern method of early and complete removal of cancerous growths has very much improved the chances of those who suffer with them.

The number of those who seem to be absolutely cured, and who prove this by freedom from disease for ten or more years, is exceedingly small; and there seems to be no period of freedom long enough to be a sure sign of cure; but the number of those who are freed from active manifestations of carcinoma for months is relatively very great. In an address before the Seventeenth Congress of German Surgeons, Professor König, of Göttingen, estimated the proportion of patients temporarily cured as high as thirty per cent.

This large percentage of comparative cures is not found in operations for cancer of the mucous passages, such as the larynx or the rectum, because in these situations a cancer is sometimes very hard to approach and hard to extirpate thoroughly, and its removal causes functional defects which are in themselves very dangerous to life. Besides this, cancers in the breathing passages, or the digestive tract, are not, as a rule, brought to the notice of the surgeon until they have already assumed formidable proportions. But, even in the case of cancers of the rectum, it is encouraging to note that the mortality has within the last ten years fallen to nearly one-half what it was formerly.

In view of these facts, the outlook for persons afflicted with cancer is very much more hopeful than it was a decade or two ago. The methods of operating are much less immediately dangerous to life, and the prospect of temporary relief from the distress and horror of a cancer is much greater.

It is very important, in estimating the value of operations for cancer, to measure, not only the months or years of life which can be credited to them, but also the amount of peace and comfort which they secure for the patient, the hope—even though it last but a comparatively short time—which succeeds to the hopeless despair of one who denies himself, or who is denied, the chances of an operation.

When all these factors are taken into consideration, we may regard with great satisfaction the attainments of the last ten or fifteen years in this field, and entertain a reasonable hope that the future may develop more accurate methods of diagnosis of carcinoma and more successful methods of operating for its relief, with a correspond-

ing improvement in the prospects of those who are the victims of its ravages.

FLUORINE AS A REMEDIAL AGENT.

The recent active search for new remedial agents has led to the introduction into medical practice of a number of new remedies, some of which have proved of real value, while others have only seemed for a time to be of service, and on more extended experience have proved of little worth. One of these agents is fluorine, an element which is well calculated to attract attention on account of its remarkable chemical properties.

In a temperate and thoughtful article in the *Deutsch-Amerikanische Apotheker Zeitung*, November 1, 1888, Dr. Theodor W. Schaefer, of Kansas City, Missouri, calls attention to the characteristics of fluorine and its compounds, and discusses its use as a medicament. He refers to the experiments of Dr. Eduard Wernigk, of Alhambra, California, who used it with satisfaction in the treatment of epilepsy, and, by subcutaneous injection, in a variety of tumors. The form which he found most serviceable was the fluoride of potassium, half-grain doses of which in solution proved of decided value in the treatment of an osteoma of the lower maxillary bone, in a fibrous tumor of the face, and in a lupoid growth of the hand. Dr. Schaefer himself used hypodermic injections of fluoride of potassium in a case of goitre, with encouraging results, and applied the remedy by pencilling and by gargling in a case of diphtheria, which ended in recovery. These cases cover the ground in which Dr. Schaefer has so far found the compounds of fluorine to be useful.

As a remedy for internal administration, the salts of fluorine have not yet given any specially good results. It has been used in certain affections of the heart, but without much success. Dr. Da Costa, of Philadelphia—whom Dr. Schaefer erroneously locates in New York—some years ago made a number of interesting experiments in the use of certain fluorides internally, and published the result of his investigations in a very instructive paper in the *Archives of Medicine*, June, 1881. This paper was a report of the first systematic attempt to use the salts of fluorine in medical practice. The salts Dr. Da Costa chiefly made use of were the fluorides of potassium and of sodium, and the ferrous and ferric fluorides. His observations led him to the conclusion that the preparations of fluorine are too irritating to the stomach to be of much value, and—as we have ascertained by personal inquiry—he does not now have a high opinion of their availability in therapeusis.

From all this it appears that the investigation of the effects of fluorine upon the animal economy has not yet led to any very important developments, and yet it certainly invites to further study. Theoretically one would expect that an agent which has such marked chemical peculiarities must have effects upon physiological and pathological processes not less marked. If heretofore it has not proved of much service in the treatment of disease, this may be because it has not been studied carefully enough or generally enough, and Dr. Schaefer has done a good thing in calling attention anew to what has been done in this direction, and in inviting the profession to pursue the investigation further.

ACCOUNTS RENDERED QUARTERLY.

There was a time when the services of physicians were not considered as an article of merchandise, with a fairly definite price, but rather as acts of benevolence and humanity, and then grateful patients signified their appreciation of these services by gifts in the nature of an honorarium. But this time has passed away, and now every medical man is compelled to keep accounts, and periodically to try to collect what he believes is due him by the unromantic method of sending out bills.

No physician need be told how troublesome and often how disagreeable a part of

his work this is. The question of what he shall charge is not rarely a trying one; for he cannot always figure out so many visits at a certain price and put this down on his bill. There are many circumstances which may compel him to make his charge less than he thinks it might properly be; and when he has fixed it, he is sometimes troubled to think it may be more—or, alas! less—than his debtor has estimated it at.

In addition to this source of distress there is the question as to the periods at which a physician shall render his accounts. In many parts of this country it has become a custom for physicians to send out bills every six months; and some men send out their bills only once a year. There are advantages in this plan for men of means and of large and lucrative practice; but it has very great disadvantages for the great majority of medical men. It is especially hard on physicians in the earlier years of their practice, because then they usually need speedy returns for their work, and treat a class of persons that requires pretty close watching. But almost all physicians lose by sending out bills only at long intervals. Patients treated with such indulgence sometimes become careless about paying, because from this very fact they imagine the doctor does not need money as they do, and some patients deliberately impose on their physicians as long as they can, and, when called upon to pay what they owe, simply transfer their patronage to someone else until his endurance is exhausted.

These and other reasons which will occur to our readers make it desirable that medical men should—except in rare cases—render bills more frequently than once or twice a year. The proper interval in most cases appears to be three months. This was the conclusion arrived at by the West Philadelphia Medical Society at a recent meeting, when the following was adopted:

"Realizing that the time has arrived when, in order to keep pace with the increasing business sentiments of the world, it is necessary to insist more strongly on the strictly business aspect of our professional services; and, believing that this will be ensured by the rendering of our accounts more frequently than has been the general custom;

"It is resolved, that the West Philadelphia Medical Society deems it to the best interests of its members, and of the profession generally in West Philadelphia, that they shall render their accounts for services quarterly or more frequently, and hereby urges upon them concerted action in this matter, reserving to them discretion to make exceptions in cases in which they may deem it to their best interests or those of their fellow-practitioners."

We fully concur with the sentiment of this resolution and believe it would be a good plan for physicians to render their accounts every three months. There are very few patients who would not approve of such a practice, and it would be a great advantage to medical men if it were generally carried out.

OPERATION FOR STENOSIS OF THE PYLORUS.

Operations for stenosis of the pyloric orifice of the stomach are no longer very rare, and a variety of methods have been proposed for treating this condition surgically, among the most promising of which was the method of digital dilatation of Loreta. Another method, which has proved of value, was first practised about three years ago by Heincke, and two years later by Mikulicz. A third operation by this method was performed in July, 1888, by Bardeleben, and is reported, with comments by Dr. A. Koehler, in the *Berliner klin. Wochenschrift*, Nov. 12, 1888. The method consists in opening the abdomen, dividing the stricture longitudinally, and then drawing the wound apart vertically so that the horizontal open-

ing is converted into a vertical one, after which the wound is united with a continuous suture. In this way the contracted tissue is made to occupy only the posterior wall of the newly formed canal, while its anterior wall is largely made up of the healthy tissue of the stomach and duodenum.

Bardeleben's operation was performed on a man, thirty-five years old, who a month before had swallowed some strong hydrochloric acid. The time consumed in the operation was only half an hour, and its result was entirely successful.

EXECUTION BY ELECTRICITY.

The law to execute criminals by electricity in the State of New York, which has just gone into effect, has led to some interesting discussion in regard to its merits and demerits. Among others the editor of the *Electrical Review* states his opposition to the law, on the ground that the execution of murderers by electricity is "an unnecessary and an unwarranted debasement of one of the most enlightening elements of the age, and that he does not believe that it is practical from a scientific standpoint." For the sake of the citizens of New York, we would hope that it may be long before they shall have an opportunity to demonstrate either the correctness or incorrectness of this opinion. Our view, however, is that the application of electricity as a means of execution of criminals is objectionable on the score of its difficulties, its uncertainty, and its effect upon the community. As we have stated before —in the REPORTER of February 11, 1888— we are of the belief that humanity no longer requires any modification in the method of executing the death sentence, and that this attempt to substitute electricity for the usual method is not in accordance with the dictates of sound policy nor justified by anything which physiologists know of the sensations connected with death by hanging.

INOCULATION FOR YELLOW FEVER.—Doctor Paul Gibier, a French experimenter, who has been studying yellow fever in Florida, proposes to establish an experimental station for treating this disease. He thinks that a safe method of inoculation will result in the prevention of the disease, and suggests that a laboratory should be established on one of the keys off the Florida coast, and a year spent in experimenting with the inoculations upon monkeys, thus perfecting a method of treatment of the fever.

BURN-BRAE VINDICATED.—Some time ago a patient suffering with acute mania was admitted to Burn-Brae, a private hospital for the insane near Philadelphia. After his dismissal he made complaint of harsh treatment and improper detention against the physicians in charge. The Committee on Lunacy of the State Board of Public Charities has investigated the complaint and has found no justification for it. In concluding his report for the Committee, the chairman, Dr. Thomas G. Morton, said that there was ample evidence to show that the patient's treatment was proper, and his recovery rapid, complete, and satisfactory.

PHOTOGRAPHY OF THE MALE BLADDER.—According to the *British Medical Journal*, Dec. 22, 1888, Mr. Hurry Fenwick, and Mr. Pearson Cooper of the London Camera Club, have been working for some time at photography of the human bladder. Various obstacles were in turn recognized and overcome, and they have now so far perfected their vesical camera and method as to obtain good negatives of the interior of "dummy" and dead bladders. They hope before very long to describe a method of recording the appearances and progress of diseases of the living bladder. The negatives are taken *per urethram* through a tube of 23 French calibre.

—The United States Steamer Yantic, which was recently sent on Government business to Hayti, is on its way home with yellow fever on board.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

173. The Significance of the Epiblastic Origin of the Central Nervous System. By George W. Jacoby, M.D., New York. From the *New York Medical Journal*, May 5, 1888. 15 pages

174. Accidents Incidental to the Use of the Exploring Needle for Diagnosis. By Hermann M. Biggs, M.D., New York. From the *New York Medical Journal*, August 18, 1888. 12 pages.

175. Osteoplastic Resection of the Foot. By Ferdinand H. Gross, M.D., Philadelphia. From the *Medical News*, October 27, 1888. 7 pages.

176. Memorial of Dr. Nathan Lewis Hatfield. By Robert J. Hess, M.D., Philadelphia. 8 pages.

177. Enterostomy for Acute Intestinal Obstruction. By B. Farquhar Curtis, M.D., New York. From the *Medical Record*, September 1, 1888. 12 pages.

178. The Failure of Dr. J. B. Thomas's Treatment of Urethral Stricture by Electrolysis. By Robert Newman, M.D., New York. From the *Journal of the Amer. Med. Association*, September 8, 1888. 15 pages.

179. Remarks on Pelvic Inflammations and the Management of their Residues. By William Warren Potter, M.D., Buffalo, N. Y. From the *Buffalo Med. and Surg. Journal*, July, 1888. 16 pages.

173. Dr. Jacoby's pamphlet contains his presidential address before the New York Neurological Society, in May, 1888, and presents an argument in favor of the view that the nervous system of vertebrates, although formed from the epiblast of the embryo, like the skin and surface epithelium, has lost its epithelial character and has returned to a state of indifference in which it is impossible to decide whether a tissue is epithelial, therefore epiblastic, or connective tissue, therefore mesoblastic.

The whole paper is exceedingly interesting, and contains very instructive suggestions as to the development of the organs of sense.

174. Dr. Biggs protests against the indiscriminate use of the exploring needle for diagnosis when other means give more reliable information. The dangers of the use of the exploring needle rest upon the traumatism produced and the risk of septic infection. The cases cited by Dr. Biggs indicate that the exploring needle should be used with caution; although it would be going too far to admit that they all illustrate the danger of its use. His warning, however, is timely and may be commended to the attention of our readers.

175. Dr. Gross describes an operation such as has been but rarely performed in this country, and not often in any country, namely that originally done in 1871 by Wladimiroff, of Russia, and independently, in 1880 by Mikulicz, of Vienna. Dr. Gross's operation was successful as far as reported; but it would be interesting to know how good use of his foot the patient has to-day.

176. This is a warm tribute by a personal friend to the virtues of a well-known medical man of Philadelphia, whose life of eighty-four years was full of useful and kindly ministration to his fellow-men, and of pleasant relations with his professional brethren.

177. Dr. Curtis has made a careful study of sixty-two cases of the formation of an artificial anus—for acute intestinal obstruction—all that he has been able to collect from medical literature—and gives the result of his analysis of their various features. It is an interesting statistical study, and of great practical value. It leads the writer of the paper to the conclusion that enterostomy is preferable to laparotomy except when the patient's condition is so good that he can bear the shock of the latter operation, and when the intestines are not so greatly distended as to offer a serious obstacle to a thorough exploration of the abdominal cavity.

178. Dr. Newman defends himself, and the operation which he advocates and practices for the cure of stricture of the urethra, against the criticisms of Dr. J. B. Thomas, of Pittsburgh, who failed to cure a case by electrolysis, and in his report of it discussed Dr. Newman's earlier report of his own experience. The defense is warm and interesting; and it is fair to say that its warmth is warranted by the terms used by Dr. Thomas in discussing Dr. Newman's methods.

179. Dr. Potter's paper presents a temperate and intelligent study of the various views as to the nature of inflammations in the pelvis of women, and a brief review of their proper treatment. The writer cites the opposing opinions of a number of well-known gynecologists, and endeavors to bring out the truth contained in what seems contradictory. The result is a very entertaining and suggestive paper, which may be recommended to the attention of our readers for their careful consideration.

Literary Notes.

—We have received the Catalogue of the Tokyo Medical Library. The library contains 1092 well-selected books and pamphlets.

—After January 1, 1889, Dr. D. A. Hodghead will succeed Dr. William S. Whitwell as Editor of the *Pacific Medical and Surgical Journal.*

—*The United Service* appears in a new series for January, 1889, with the name of L. R. Hamersly & Co. as publishers. It is a handsome large octavo of 116 pages, containing a number of interesting papers by military and naval officers, and the announcements of the editor and of the publishers, short notes, and news of the Loyal Legion. Those of our readers who have served in the army or navy will be interested to know that the publication of this journal has been resumed, and that it promises to be more interesting in the future than it has been in the past.

—From and after the first of January, 1889, *The Canadian Practitioner* is to be published as a semi-monthly, instead of a monthly, as heretofore—twenty-four issues in the year being given, instead of twelve. *The Practitioner* is now about to enter on its fourteenth year, and its history has been one of steady progress and development. At the beginning of 1888 a great improvement was made in the typographical appearance and material make-up of the journal, and its prospectus for the coming year promises still further advances. The subscription price remains what it was formerly: $3 00 a year.

CORRESPONDENCE.

The Porro-Cæsarean Method of Mr. Lawson Tait, historically examined.

TO THE EDITOR.

Sir: In the *British Medical Journal* for November 17, 1888 (see also the REPORTER, January 5, p. 30), we find the following from Mr. Tait: "I have now done four operations on the principle laid down by Professor Porro, and all the mothers have recovered, and the children have all lived. The operation I perform is certainly not Porro's operation, for I have altered nearly every detail."

"My own method of operating is to make an incision through the middle line large enough to admit my hand, and then I pass a piece of india rubber drainage tube (without any hole in it) as a loop over the fundus uteri, and bring it down so as to encircle the cervix, taking care that it does not include a loop of intestine. I then make a single hitch and draw it tight round the cervix so as completely to stop the circulation. I give the ends of the tube to an assistant, who keeps them well on the strain, so as to prevent the loose knot from slipping, the reason of this being that should there be any bleeding and any necessity for further constriction, I could secure this in a moment, without undoing any knot, and the simplicity of the method greatly commends it. I then make a small opening in the uterus, and enlarge it by tearing with my two fingers, seize the child by a foot and remove it. I then remove the placenta, and by that time the uterus has completely contracted and is easily drawn through the wound in the abdominal wall. The constricting tube will now probably require to be tightened, and the second hitch of the knot may be put on at the same time, and the work is practically done. Stuff a few sponges into the wound to keep the cavity clear of blood, and pass the knitting needles" (2) "through the flattened tube and through the cervix, and in this simple way a clamp of the most efficient kind is at once made. The uterus is removed about three quarters of an inch above the rubber tube. The usual stitches are put in, the wound closed round the stump, which of course is brought to the lowest part of the opening, and then the stump is dressed with per-chloride of iron in the usual way."

This is certainly in many respects, an excellent way to operate, and Mr. Tait has shown his wisdom by accepting and grouping together a series of alterations made and tested before he ever operated. His altering, does not mean, that he claims to have originated the alterations. The Esmarch tube and transfixing pins are in very frequent use.

The opening of the uterus *in situ*—the delivering of fœtus by the feet—the constriction of the cervix—and securing the stump in the wound after its amputation, are the points of the operation as performed by Prof. Porro. The alterations in the details are as follows

1. *The constriction of the cervix, after the manner of Esmarch;* as applied first by Prof. Litzmann of Kiel, now of Berlin, in case 15, in chronological order, on June 14th, 1878. The elastic ligature was used to continue the constriction, instead of the *serre nœud* or clamp. Elastic ligation was also employed in case 71, Dec. 7, 1880, under Dr. J. De Rull of Barcelona, Spain, and in case 72, of the same date, by Prof. Hegar, of Freiburg, Germany.

2. *Opening the uterus by small incision and enlarging the opening by digital laceration;* as introduced by Dr. Clement Godson, of London, on November 27, 1882; who says in his report, "I made" . . . "a small incision, large enough to admit the finger" . . . "I immediately inserted the tips of each fore-finger, and tore the womb open transversely." There is no necessity to tear the uterus, where the elastic tube of Esmarch is used.

3. *The transfixing of the cervix by two long pins or knitting needles.* Prof. Chiara of Milan lost a case in December, 1877, by the stump falling in and the bowels protruding, as the result of vomiting: in his next operation, May 22d, 1878, he made use of one transfixing pin as a preventive. Six days later, Prof. Domenico Tibone, of Turin, introduced the plan now in general use, of employing "two long transfixing pins." It is also the custom of some operators to stitch in the cervix with the abdominal wound, to secure an early and intimate union, as a means of safety.

Half-knotting the Esmarch tube, as practised by Mr. Tait, is better than whole knotting it, and then being obliged to untie and retie. Clamping the half-knot by strong pressure-forceps is a common mode of security. Passing the pins through the tube instead of beneath it, belongs to Mr. Tait. As the pins come away with the tube when the stump separates, they will fail of the purpose for which they were originally

introduced in Italy, if separation should happen to take place too early. The pins fix the stump, and secure it from being kept in slipping motion excited by vomiting, by respiration, and the dragging upon it from within, all of which have a tendency to delay union. The chief value of the pins is in the first few days, and their office ceases with the union of stump and abdominal wall: hence the additional advantage of cervico-abdominal suturing, through the tissues which are to remain after the pins come away. Much temporary disfiguring of the abdomen in the line of the cicatrix, by its being deeply drawn in, remains in many cases. Where there is extreme antero-posterior pelvic collapse, as in rickets, and the sacro-vertebral angle is so altered as to bring the plane of the superior strait nearer in parallelism with the abdominal wall than normal, there will be the least vagino-cervical tension, and *vice versa*, when the pelvis is normal, as in tumor cases. In time, the stretching of the stump within, relieves the abdominal wall from being deeply indented.

The Porro-Cæsarean operation is much more of a principle, than of a special method devised by the Pavian professor, and departures from the technique of his original plan, do not in the least weaken the claim which associates his name with the operation as a whole. Prof. Porro designed to save life, by giving the uterus a form of wound after a Cæsarean delivery, that might be dressed outside of the abdominal cavity, and by which septic peritonitis could be avoided. The quasi unsexing of the woman was scarcely to be considered; as her living, to become again pregnant, after the old operation was a great rarity in Italy. Her being made sterile is now claimed as an advantage by many operators. Professor Porro by saving five women out of a record of six, has shown, that his own technique has a high capability of securing success. As supra-vaginal hysterectomy existed before Prof. Porro applied it in parturient cases, it is an error to attach his name to any hysterectomy case which is not "completive of the Cæsarean section." To remove an unopened uterus for tumor, and with it a fœtus in the early months, is not strictly a Porro operation, and such cases have no claim to enter into a statistical record of Porro cases, as the fœtal column can have but one result, and that a fatal one: the same may be said of hysterectomy following a rupture of the uterus.

The Porro-Cæsarean section has at this time an additional interest from the fact, that the records of the last four years show a very decided decrease in the percentage of deaths over that of former years. A full record of 1884, shows 28 Porro operations, with 18 women and 10 children lost. This appears to have been the maximum year for cases, with the exception of 1880, when there were 33, with 22 deaths. Since the introduction of the Sänger method, there has been a gradual falling off in the number of Porro operations, and at the same time an increase in the percentage of women saved under each: viz., in 1885 there were 13 Sänger operations with 4 deaths: in 1886, 33 operations with 10 deaths; and in 1887, 47 operations with 10 deaths. In 1885, there were 22 Porro operations with 5 deaths, and in 1886, 22 operations with 4 deaths. There may be possibly a few Porro cases for these two years not yet collected: the record of 1887 is very incomplete as yet, showing twelve cases, with two deaths and one suicide. The reports of 1888 are thus far equally encouraging.

Mr. Tait strongly advocates the Porro operation in preference to the Sänger, but strangely withholds from publication three cases, that might add force to his claimed preference. As we do not know even the years of their performance, they are as yet useless in the comparison.

Since the above was written, I have learned that Mr. Tait, in an operation performed last June, used the Esmarch tube temporarily; then applied his own modification of Kœberlé's *serre nœud;* and secured the stump by a "fixation pin," like a large hair-pin, with trocar points and caps to cover them. This is, then, his proper and last method of operating.

Yours truly,

ROBERT P. HARRIS, M.D.
329 S. 12th Street, Philadelphia,
December 24th, 1888.

Typhoid Fever in West Virginia.

TO THE EDITOR.

Sir: Since Aug. 1, 1888, we have had an epidemic of typhoid fever here in the mountains. Where it comes from, or what is its prime cause, I am unable to say. The country here I believe to be healthy. We live on a large river—the Clear—in Tucker County, West Virginia, and our drainage is good. There is a new railroad being built through this region, and some believe the typhoid fever is due to the stirring-up of the soil. The water I do not think the best,

and there is a great deal of decaying vegetable matter also through this country.

I have had cases in the healthiest localities and cannot understand it except that, as an epidemic, it must be everywhere. All cases, if sent away in time, soon get well; those that stay generally suffer.

I have talked to my brother physicians on the subject and they give me little satisfaction. I write to ask for information. I am young in the profession, and need help, and wish to learn all I can. The REPORTER helps me, and whenever I see anything of typhoid fever, especially, I at once wish to see if I can get what I wish. Now, tell me: what is it that might have started it here? As far as I can learn, the first case was seen by a doctor some eight or ten miles from this point, some time early in May. The epidemic started on the railroad above this place, among some negro railroad hands. Doctors Porter, Harr, Baker, and I had the camps moved to a dryer place, and soon had no return of the trouble there. It is now all over our country and we still fight it. I have advised cleanliness about the houses and yards, have used disinfectants, have begged the people to use lime, both in and about the houses; but still we are kept on the go to see new cases. Let me hear from the readers of the REPORTER. I would like to hear from other physicians on the subject of typhoid fever—giving the means of preventing its spread and their treatment of cases, etc.

Yours truly,

B. M. SMITH, JR., M.D.

Parsons, W. Va.,
Dec. 17, 1888.

Long Continued Diabetes Mellitus.

TO THE EDITOR.

Sir: I saw in the REPORTER, November 10, 1888, a short article by Dr. Henry C. Coe, about albuminuria in diabetes mellitus and its conclusions. I have at present a patient, 69 years of age, who had for fourteen years glycosuria, and has now albuminuria, but no diabetes any more. It is about a year he developed the nephritis; urine, sp. gr. 1.005, albumin 2 per cent., fatty, hyaline casts, with some blood and pus casts; latterly he commenced to have abundant epistaxis; at one time the attacks continued for a whole week, the patient losing sometimes more than a pound of blood daily. Now he loses a few drops of blood once in a while. His heart is rather weak, and he has slight swelling of the extremities; but his appetite is pretty good, his mind is clear, and he is not at all emaciated. His urine is abundant and acid; and acetone is also present in it. The patient has been formerly a hard drinker. I would not be surprised if he should die of coma. I only cite this as a case of long diabetes, apparently without much harm; but I think this chronic nephritis brought on by the irritation of the kidneys through frequent micturition. Besides, he will not take any medicines nor observe any diet; only when he is much frightened, as in the bleeding from the nose.

Yours truly,

VALENTINE KAUFMANN, M.D.

Catorce, Mexico,
Dec. 7, 1888.

NOTES AND COMMENTS.

Splenectomy.

Mr. G. A. Wright, in a communication on splenectomy in the *Medical Chronicle*, Dec., 1888, says that splenectomy has been performed for the following conditions: painful floating spleen; painful "hypertrophy" of the spleen; malarial enlargement; cystic enlargement, whether from the presence of hydatids or from the development of simple cysts of unknown origin; abscess of the spleen; enlargement in leukæmia; tumor of the spleen. He has collected records of 62 cases. Twenty-two cases of leukæmia were operated on with fatal result in every case except one, which is classed, not as an instance of leukæmia, but of hypertrophy, by Thornton, Collier, and Crédé. This case is that of Franzolini. The cause of death in 12 cases was hemorrhage. In 5 of these the patient did not live more than one hour. Three patients died of shock, one of peritonitis, only one survived for twenty-four hours, and the longest recorded survival was forty-eight hours, except in one doubtful case.

Twenty-three cases are classed as hypertrophy. He suggests that probably in some of these, as in a case of his, there was chronic perisplenitis. Of the twenty-three, 15 died, the most common recorded cause of death being hemorrhage, which killed four patients. The cause of death is, however, not stated in the majority of the cases. In three of the cases that died of hemorrhage, including his own patient, the bleeding came from a vessel in the diaphragm. This was also the cause of death in one of the cases of leukæmia. There is not sufficient evidence to show any

relation between the weight of the spleen and the mortality of the operation.

In seven malarial cases there were five recoveries, if one is included that lived for 35 days, and then died, apparently of old nephritis and peritonitis. In this series there seems to have been no relation between the size of the spleen and the mortality.

Three patients with cystic disease all recovered. Five of unenlarged, or only slightly enlarged, "floating" spleen all recovered. In two of the successful malarial cases the organ was also "floating," as well as in one of the cases of hypertrophy, in which recovery occurred.

The more recent operations in cases of hypertrophy show a marked improvement over the older records.

In the vast majority of cases in which the sex of the patient is recorded the patients were females.

The conclusions at which he has arrived from a study of these cases, he presents as follows: 1. Splenectomy for leukæmia is inadmissible. 2. Splenectomy for hypertrophy is very dangerous, the chief danger being from hemorrhage and shock, and there being especially danger of bleeding from a vessel that passes between the spleen and the diaphragm. Whether it is altogether an abnormal vessel or merely a dilatation of a small vessel existing there, he says he does not know, but it is responsible for the death of his patient, and for that of three others, including a patient with leukæmia. 3. If malarial patients require removal of the organ there is a good prospect of recovery. 4. Cases of floating spleen and of simple cyst are eminently favorable for operation. 5. From a special consideration of his own case, he says that in a patient with simple hypertrophy or chronic splenitis, whichever it may be, a careful examination of the relations of the organ should be made before dividing any vessel, and if large adhesions to the diaphragm are found, and the spleen is firmly fixed, and the pedicle broad and ill-defined, the operation had better be abandoned. It is, of course, impossible to stop if once there is any laceration of the splenic tissue, since the bleeding can only be arrested by removal of the organ. If removal is found to be impracticable after opening the abdomen, the question of ligature of one or more of the main vessels supplying the spleen, is worth considering. Ligature of the splenic artery was suggested by Lucas, but has, so far as Mr. Wright knows, never been tried.

Successful Gastrostomy.

At the meeting of the Southern Surgical and Gynæcological Association, held at Birmingham, Ala., Dec. 4, 5 and 6, Dr. W. B. Rogers, of Memphis, Tenn., reported a successful case of gastrostomy, which he had performed for relief of a patient with cicatricial stricture of the œsophagus. The patient, a white man, 24 years of age, swallowed a solution of concentrated lye one year before the operation. The contraction was situated seven and a half inches from the incisor teeth. The opening was so small that repeated examinations failed to pass it with the smallest urethral bougies. The patient's flesh and strength were rapidly failing from starvation.

Operation, June 29, 1888. Fenger's incision was made; the stomach was held in the abdominal wound by means of hare-lip pins, and stitched to the abdomen with silk. Every aseptic precaution was taken, and the patient recovered without any serious symptoms. On the tenth day, the gastric opening was made, and fifteen weeks later the patient was in excellent health, with flesh and strength fully restored; ability to swallow solid food had gradually returned, and though the opening was not being used, it gave no trouble, the edges having fully cicatrized.

Treatment of Shock.

In some remarks of the treatment of shock, in the *Therapeutic Gazette*, Dec., 1888, Dr. H. C. Wood says that the most characteristic symptoms of shock are the great loss in the force of the pulse, the height of the arterial pressure, and the extraordinary fall of the bodily temperature. He suggests that the unconsciousness which comes very late in shock is due to failure of blood-supply to the brain and the lowering of the temperature of the cerebral mass. The chief cause of the heart failure is the lack of resistance to its contraction caused by the vaso-motor paralysis, which also accounts for the great fall in temperature.

If these physiological views are correct, the two chief indications for the treatment of shock are to overcome the vaso-motor paralysis and to maintain the bodily heat. Stimulation of the heart is, of course, useful, but such stimulation will amount to very little if there is no reawakening of the resistance to the heart action; and if such resistance is aroused in any individual case, it is almost certain that it in turn will re-excite the heart.

With regard to the propriety of giving liquid food in cases of shock, Dr. Wood points out that in severe shock digestion must be in great part, if not altogether, arrested; and the advisability of putting food into the stomach seems to him very doubtful. Raw meat-juice, or better, beef essence, highly seasoned and given hot, is a stimulant rather than a food, and may achieve good at a time when so simple a true food as milk might be actually dangerous.

He advises for the maintenance of body-heat either the hot bath at 110° Fahr., or the hot-water bed. The latter is almost as powerful, he says, as the former, and is free from its objections. If an ordinary water-bed is filled three-quarters full of water at a temperature of 130° or 140°, and blankets spread over it, and the patient laid thereon, his body will sink down so that it will be almost surrounded by the heated mass. If the bed is well covered with blankets many hours will be required for the cooling of the water, so that the body heat can be kept up for a length of time without the patient being disturbed. Dr. Wood says he has found this method of heating the body in collapse extraordinarily efficacious by practical trial.

With regard to the choice of medicines in surgical collapse, he reiterates his well-known opinion that as the action of ether and of alcohol is practically identical, the use of the latter as a stimulant in collapse from the former is improper.

In shock unconnected with anæsthesia, atropine hypodermically is very valuable by virtue of its action as a vaso-motor stimulant. If ergot is used, it should be in the form of the official aqueous extract, five grains dissolved in ten minims of water with two minims of glycerine and ½ minim of carbolic acid. Digitalis, he says, is strongly indicated in shock, not only on account of its power over the heart, but because it appears to be a powerful vaso-motor stimulant. It might be injected directly into a vein in extreme cases; in this case its effect would be immediate but very temporary. Dr. Wood says that he is not aware that anyone has ever proposed the intravenous use of the drug in collapse or shock, but he commends it for trial as practically free from danger, unless over-doses are given, and says it offers the possibility of a brilliant and novel result. Five minims of the tincture diluted with a drachm of distilled water might be *slowly* injected, and repeated or increased *pro re nata*.

Creolin in Eye Diseases.

Dr. J. H. Thompson, of Kansas City, Mo., in a communication to the *Kansas City Med. Record*, Nov., 1888, says that for many years, in certain diseases of the cornea, he has used powdered iodoform and the ointment, which are introduced into the eye two or three times a day in sufficient quantity to bring the antiseptic in immediate contact with the ulcer. In other cases he has had recourse, sometimes exclusively, sometimes in conjunction with the drug mentioned, to an application to the inverted lids and cornea of a solution of the nitrate of silver (1 to 40). The result of this treatment, prolonged two or three months, has been nearly always satisfactory; but to obtain a radical cure it was often necessary to continue the treatment three or four months. He says he has found cases, however, in which this treatment has given but incomplete results; the inflammation diminishes, the functional troubles disappear almost entirely, and the patient is satisfied, believing himself cured; yet when the cornea is examined through a strong lens, small ulcers are seen on its surface, showing that the epithelium has not been completely reproduced. These ulcers, under certain special conditions, may occasion a relapse. Under these circumstances it is imperative that we should seek other remedies which can more completely and certainly destroy the micro-organisms in the cornea.

It is in these cases that he has tried creolin, and he expresses himself as much pleased with it. At present he only speaks of its healing virtues in two cases.

Creolin is a product of the decomposition of coal-tar. It comes now as a brownish liquid, very complex and very impure. It smells like tar, and it is slightly irritating to the cornea, as all the phenols are, for it is strongly acid and slightly caustic. It is probable that before long it will be purified, when it will be as neutral as vaseline, and will then be of even greater value to the ophthalmologist than it is now. Its antiseptic properties are undoubtedly superior to all other drugs at our command.

Dr. Thompson uses creolin in the following manner. A solution is made of:

℞ Creolin . . . . . gr. iss
Aquæ destil. . . . . ℥cl

With a brush dipped into this solution he touches the ulcers once or twice a day, after anesthetizing the eye with cocaine. Sometimes he uses a spray of creolin:

℞ Creolin . . . . . gr. viii
Aquæ destil. . . . . f℥iii

This fluid is sprayed upon the eyeball for a moment or so five or six times a day. With this treatment he has generally obtained rapid healing of the cornea in from one month to six weeks, while with other remedies he has had only incomplete success.

Peripheral Neuritis.

At the meeting of the Nottingham Medico-Chirurgical Society, Nov. 16, 1888, Mr. T. D. Pryce read a paper on this subject. Having discussed the chief types of multiple neuritis, he especially alluded to diabetic neuritis, stating that this disease might occur in two forms: (1) one in which the motor nerve-fibres were chiefly affected, with consequent paralysis; seen in some cases of advanced diabetes; (2) a form in which the sensory, vasomotor, and trophic nerve-fibres were mostly implicated, with consequent and corresponding symptoms. This type closely resembled locomotor ataxia, and also that form of alcoholic neuritis described by Dreschfeld as alcoholic ataxia. Mr. Pryce suggested the term diabetic ataxia or diabetic pseudo-tabes. He related three cases illustrating this form of disease, in one of which extensive peripheral neuritis was found after death. He considered that the diabetic poison was peculiarly apt to affect the peripheral sensory nerves, and in support of this view instanced the comparatively frequent occurrence of symmetrical neuralgia in diabetes. He further drew attention to a suggestion made by him, two years before, as to the nature of the ataxia which so often occurred in diabetes, and believed that it was in many cases due to a peripheral sensory neuritis. A case of peripheral neuritis associated with phthisis was also related. The patient was a woman, 57 years old, and presented most of the typical symptoms of the disease, namely, pains of varying character, anæsthesia, impairment of superficial reflexes, loss of knee-jerk, tenderness of muscles to pressure, together with muscular paralysis and atrophy. The disease had run an extremely chronic course. Peripheral neuritis was found after death. In this case there was no history of alcohol, syphilis, rheumatism, etc. The paper was illustrated by drawings, photographs, and microscopic specimens of alcoholic, diabetic, and idiopathic neuritis. — *British Med. Journal*, Dec. 8, 1888.

Accidental Rashes in Typhoid Fever.

At the meeting of the Royal Academy of Medicine in Ireland, Nov. 16, 1888, Dr. J. W. Moore made a communication on accidental rashes in typhoid fever. He explained that it was not his intention to allude to the essential rose-spot rash of typhoid fever; or to the more common epiphenomena of the disease connected with the skin, such as *taches bleuâtres*, purpura spots, vibices, and sudamina or sweat vesicles; or, lastly, to the coexistence with typhoid fever of other specific diseases showing characteristic eruptions, such as scarlatina, measles, variola, and, above all, typhus. He desired rather to draw attention to certain other accidental or adventitious appearances of the skin, which were of somewhat rare occurrence, and, from a diagnostic point of view, of considerable importance. These were (1) simple hyperæmia; (2) miliary eruptions; (3) erythematous rashes; and (4) urticaria. Dr. Moore then detailed a series of cases which exemplified the occurrence of these accidental rashes, and summed up as follows: 1. Not infrequently, in the course of typhoid fever, an adventitious eruption occurred, either miliary, urticarious, or erythematous. 2. When this happened, a wrong diagnosis of typhus, measles, or scarlatina respectively might be made, if account was not taken of the absence of the other objective and subjective symptoms of these diseases. 3. The erythematous rash was the most puzzling of all; but the prodromata of scarlet fever were absent, nor was the typical course of that disease observed. 4. This erythema scarlatiniforme was most likely to show itself at the end of the first, or in the third, week of typhoid fever. 5. In the former case it probably depended on a reactive inhibition of the vasomotor system of nerves; in the latter, on septicæmia, or secondary blood-poisoning; or both these causes might be present together. 6. The cases in which this rash appeared were often severe; but its development was important rather from a diagnostic than from a prognostic point of view. 7. Hence, no special line of treatment was required beyond that already employed for the safe conduct of the patient through the fever.

Dr. Duffey asked if there had been eliminated the possibility of the rash being due to drugs administered during the course of the disease. He had himself seen four cases of profuse miliary eruption following the administration of antipyrin. So, too, an erythematous eruption similar to scarlet

fever followed the administration of quinine, while scarlatinal eruption followed the administration of antipyrin, salicylic acid, and other drugs. Rashes occurred in fevers attended with serious blood-changes, and disappeared without any marked effect on the patient.

Dr. Pollock pointed out as remarkable that while most writers observed that the rash occurred in the first week or early stage of the fever, in a case of his the rash did not appear until the third week, although the rose spots had been out for a fortnight before. The pulse was never very high, but on the night of the 18th it suddenly rose to 108, and the rash was then noticed coming out over the back, chest and abdomen. Next day there was a sudden collapse—the temperature fell to 96°, and the pulse was low and very weak. On the following day Dr. Moore saw the patient, and on the day after the rash came out over the extremities. In reference to the medicines administered, he had given two grains of quinine, but, as it made the patient deaf, he stopped, and no more was given until after the erythematous rash disappeared. No antipyrin had been given.

Dr. Walter Smith said there were drug rashes and food rashes; and the explanation given by Dr. Duffey applied to many cases. Most rashes belonged to the erythematous class, and were due to a transitory disturbance of the vascular system of the skin, liable to arise in four different ways: First, direct action on the central nervous system by drugs; secondly, reflex irritation from the intestinal tube, produced by articles of diet; thirdly, direct dilatation of the vessels of the skin caused by such drugs as nitrite of amyl, nitro-glycerine, and alcohol; and, fourthly, the diffuse transudation of irritating drugs through the skin, as the essential oils of copaiba and cubebs, etc.

Dr. John William Moore replied that in Case No. 1, no medicine had been administered for some days, and the only possible cause of the efflorescence was the extreme rise of temperature, followed by sweating. It was not true erythema, but an efflorescence on the skin. In Case No. 2, he understood that the patient had been getting morphine to produce sleep, but only in small quantities; and that drug could scarcely have had anything to do with the development of the miliary eruption. In Dr. Pollock's case, quinine in only two-grain doses had been given several days before the rash appeared, but it disagreed, and was stopped.—*British Med. Journal*, Dec. 1, 1888.

Disinfection of the Air-Passages with Myrthol.

The Vienna correspondent of the *New Orleans Med. and Surg. Journal*, Dec., 1888, says that hitherto inhalations of turpentine in the respiration mask of Curschmann have been used for disinfecting the air-passages, or for combating putrid processes. Aside from the frequent disagreeable after-effects which were produced by this medication, the results also were very little favorable. In spite of the inhalations a patient affected with putrid bronchitis used to infect a whole ward in the hospital. Dr. Eichherst has recommended a medicament which, taken by the mouth, met all these inconveniences, and moreover favorably influenced the appetite and the general condition of the patient. This drug, myrthol, has a rapid and sure effect. It is that part of the myrtle-oil which boils at from 160° to 170° C. (320° to 338° F.), and which represents a clear fluid of an aromatic odor. It had formerly been recommended as a deodorant in bronchial catarrh. According to the present recommendation it is the best medicament for rapidly and surely combating the putrescence, and for removing the bad odor of the breath and the secretions.

When a gelatine capsule containing two and one-half minims of myrthol is taken the breath distinctly smells of myrthol for an hour, and this odor can also be perceived for twenty-four and even forty-eight hours after the administration. In putrid processes much larger doses are required; in most cases two capsules are administered at intervals of two hours. There is no disgust against the drug on the part of the patients.

Though myrthol proves very effectual in combating the putrid process and the bad odor connected therewith it is quite ineffectual for preventing an infection with tubercle bacilli, as tuberculosis developed even when myrthol was in use.

New York Academy of Medicine.

At the meeting of the Academy January 3, 1889, the annual reports of officers and committees were read. The total amount of money in the permanent fund is $120,776.85. The library has received during the year 1888 2,600 volumes, 3,235 pamphlets, 17,452 medical journals. Four thousand dollars was granted to the library for expenses during the current year. The number of members has been increased by 55.

NEWS.

—Dr. Horace Jayne will succeed Prof. E. Otis Kendall as Dean of the College Faculty of the University of Pennsylvania.

—Dr. C. N. Campbell, of Poughkeepsie, N. Y., died December 20. He was graduated from the Medical Department of the New York University in 1848, and was President of the Poughkeepsie Civil Service Board.

—Press dispatches indicate that smallpox exists in widely separated portions of this country. It is reported to be spreading in Albany, N. Y., and the inmates of Auburn State Prison are to be vaccinated. It is also increasing in New Washington, Ohio, to such an extent that business has been interfered with and trains are not allowed to stop. A few cases are reported from Newport, Kentucky.

—The Mills Training School for Male Nurses, in New York, was opened December 19. There were 110 applicants, of whom 22 were admitted to the school. The *Doctor* says: "The old Reign of Terror in many of our hospitals is drawing to a close. The Warden of Bellevue Hospital began discharging the orderlies in the wards for male patients the other day, and filling their places with the students just admitted to the new Mills school for training male nurses. Now the male patients will probably be as skillfully nursed as the female patients have been for some time."

—The New York *Medical Record*, January 5, 1889, says that the statistics of the New York State Board of Charities for the year ending October 1, 1888, show only a little increase in the number of the dependent classes other than the insane, and in the expenditures during the year as compared with last year. The whole number of insane in the institutions of the State on October 1, 1888, was 14,772, as against 14,062 on October 1, 1887, an increase of 710. This is the greatest increase in any year in the history of the State. All of the asylums are full, and many are greatly overcrowded.

Doubtful Customer.—"Are these 'ere specs genuine crystal?" Street-stand merchant: "Chenooine? Of you don't mention it, I tell you someding. My bruder Isidore has bought dot Crystal Palace in England and is cutting him up into spectacles—dot makes dem so cheap. One dollar an' a halluf a pair!"—*Puck.*

HUMOR.

A match between two dentists in their art would probably result in a draw.—*Boston Courier.*

Wanted the Free List Extended.—Big Brother College-Graduate—"Are you in favor of wool being free of all duty?" Undergraduate (with conditions)—"Yes, sheepskins too."—*New Haven News.*

Miss Keane (to handsome young physician)—"Oh, doctor, how do you do? You look killing this evening!" Young Physician (quietly)—"Thank you, but I'm not; I'm off duty, don't you know."—*Drake's Magazine.*

Someone who has given attention to the subject says that anodynes are laborious in their operation. The discovery lacks the merit of originality, however. It has long been known that anodynes are pains-taking.—*Binghamton Leader.*

The other way about.—Irate passenger (as train is moving off)—Why the —— didn't you put my bagge ge in as I told you, you old ——? Porter—Eh, man! yer baggage es na sic a fule as yersel'. Ye-re i' the wrong train.—*London Punch.*

"How much will a new set of teeth cost?" "Fifty dollars, madam." "Oh, that is much too dear!" "But, madam, think: you will be able to eat with them." "Yes, but if I pay so much as that I will have nothing to eat."—*Fliegende Blätter.*

It is said that "a Dakota girl ate twenty ears of green corn for supper and then went to a party and danced all night." We should think she would. Eight ears of corn are enough to make some people dance all night—and howl, too.—*Norristown Herald.*

Johnny—"Pa, this paper says that Mr. Smith died intestate. What does that mean?" Pa—"It means, my son, that—er, that Mr. Smith had something the matter with his intestines—some sort of inflammation of the bowels, probably." *Boston Transcript.*

A Long Term.—Irish guide to American tourist—"And there is no King nor Quane nayther in America, they're tellin' me, sur?" Indifferent Tourist—"No; we've a President there." "And how long have you been havin' a President, moight I ax, sur?" I. T.—"Oh, something over a hundred years!" Irishman, stopping, paralyzed with astonishment—"Howly saints! And do they live that long beyant there?"

MEDICAL AND SURGICAL REPORTER

A WEEKLY JOURNAL

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

FOR THE CURE OF
NERVOUS HEADACHES

EFFERVESCENT
BROMO
(WARNER & CO.)
SODA

℞ Caffein 1 grain, Brom. Soda 30 grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a remedy in Seasickness and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Brom. Soda 30 grs., and Caffein 1 gr., in half a glass of water, to be repeated once after an interval of thirty minutes if necessary.

EFFERVESCENT
BROMO
(WARNER & CO.)
POTASH

℞ Caffein 1 grain, Bromide Potash 20 grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a remedy in Seasickness and Epilepsy.

☞Physicians desiring the Potash Salt can obtain the same by ordering or prescribing Bromo-Potash (Warner & Co.) the composition of which is: Brom. Potash 20 grs., Caffein 1 gr.

PREPARED ONLY BY
WM. R. WARNER & CO.
ORIGINATORS AND MANUFACTURERS OF
Bromo-Soda, Bromo-Pot sh. Chalybeate Saline, Triple Bromides, etc.

CAUTION.—It is necessary to specify (WARNER & CO.) to prevent the substitution of other "Bromos," the composition of which is not made known.

SUPPLIED BY ALL REPUTABLE DRUGGISTS.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

OSTEOTOMY FOR ANTERIOR CURVATURES OF THE LEG.[1]

BY DE FOREST WILLARD, M.D., PH.D.,
PHILADELPHIA.
LECTURER ON ORTHOPÆDIC SURGERY, UNIVERSITY OF PENNSYLVANIA; SURGEON TO PRESBYTERIAN HOSPITAL; CONSULTING SURGEON TO THE WHITE AND TO THE COLORED CRIPPLES' HOMES.

One of the most frequent deformities produced by rickets is a forward arching of the bones of the leg, which deviation is very often associated with a lateral curve of both tibia and fibula.

Rickets is a constitutional disease, and is so seldom seen in country practice in healthy districts, that physicians frequently overlook the early symptoms, which are manifested by an indisposition of the child to be lifted, by peevishness, and by general symptoms of mal-nutrition. Ordinarily these conditions are attributed to indigestion, and certainly the stomach and intestines are largely at fault in the production of this state of defective digestion, and still more defective assimilation; but simple indigestion does not give the beaded ribs or "rickety rosary," the softened cranial bones, the cranio-tabes, the lengthened dolicho-cephalic skull, the open fontanelles, the softened bones, the enlarged epiphyses, the excessive head sweatings, the flabby muscles, and the enlarged epiphyses—deformities so characteristic of rachitis. Rickets is essentially a disease of early childhood, is rarely congenital or hereditary, and only occasionally develops at or after puberty. It differs entirely from either tuberculosis or scrofulosis.[1] In small cities it is rare; in larger ones, it is found in proportion to the exist-

[1] Read before the American Orthopædic Association, September, 1888.

[1] Ashhurst, International Encyclopædia of Surgery, Vol. I; p. 251.

ing amount of filth, squalor, bad air, scanty food and deficient light. When found in the rich, it can be traced to improper food or hygiene. In this country the colored race is more affected than the white, and the results are also more serious.[1]

While it is a constitutional disease affecting all the tissues of the body, yet its worst manifestations are exhibited in deformities of the bones. These deformities are due to the relative preponderance of the organic over the earthy tissues in the bone, and the failure of the formative cartilage cells to produce true bone cells. This is the stage of softening; and during its progress, if the child is allowed out of bed, the osseous tissues are unable to sustain the superincumbent weight and consequently easily yield to a greater or less degree. Not only do the tibia, fibula and femur become bent, but the pelvis is deformed, and either from creeping or from being lifted, the humerus, or the radius and ulna of the patient, may also be distorted. In severe grades even the clavicles are arched.

Upon the resumption of proper assimilation, however, the deposit of earthy salts begins, and then follows the stage of *sclerosis* or hardening, which permanently fixes the distorted bones in their faulty positions.

Among the most frequent of bone deviations are *anterior tibial curves*. These are not produced by contraction of the gastrocnemius; for the calf-muscles are at first flabby and only become shortened at a later stage. The distortion may extend in a long curve from knee to ankle, or it may be abrupt and angular at any portion of the bone, usually the lower third.

The treatment of these anterior curves is accomplished by

I. Manual Straightening and the Use of Apparatus.

In the second and third years of life, if the bones are still either soft or springy, it is possible to correct the deformity by frequent manual straightening, provided the mother or nurse is willing to give the requisite time and patience to the case. The pressure should be as forcible as the integrity of the bone will permit; this will give the child pain for only a few moments after the force is removed. This pressure should be repeated many times daily. If gentle manual pressure could be constantly applied it would doubtless, as in club-foot, be perfectly curative. Instrumental pressure, made in the proper direction by spring power or by strap connected with steel uprights, may be employed in connection with manipulation, during this stage.

After the bone has hardened, however, I agree with Gibney[1] in saying that I have never seen a case of anterior curve of the tibia of any magnitude reduced by apparatus. Many surgeons spend months in attempting to straighten the bones in these cases, and then condemn the patient to perpetual cripplehood; whereas a slight operation will produce a perfect cure. The conditions are mechanically entirely different from those met with in legs bowed laterally.[2]

II. Forcible Fracture.

A. *By the Hands.*
B. *By the Osteoclast.*

A. *Manual Fracture.* — In children under three years of age, by far the safest and best plan to be adopted, is fracture of the two bones at the proper point, if the surgeon possesses the requisite strength. For additional power the knee may be used, or the child may be placed upon its face and a very small sand-bag, or a wide roller bandage, be used as a fulcrum. Frequently it is timidity rather than lack of strength that prevents success. Up to the point compatible with the life of the soft parts, its great advantage lies in the fact that only a simple fracture is produced and speedy union is the result.[3] The objection to the plan lies in the inability of the surgeon to regulate exactly the point of fracture.

The proper dressing after manual fracture is fixation, as described under osteotomy.

B. *Osteoclasis.*—The osteoclast, while a very efficient instrument in the thigh, yet in the leg has the great disadvantage that pressure must be made upon the sharp edge of the tibia covered only by thin skin. It offers the advantages, however, that in the centre of the bone pressure can be applied to a definite point, and that its resultant is a simple fracture, provided sloughing is avoided. When the apex of projection is near to either epiphysis, however, neither

the Rizzoli pattern nor any of its modifications is easy of adjustment.[1]

III. Osteotomy.

A. *By chisel:* 1. Simple. 2. Cuneiform.
B. *By saw.*

A. *Chisel.* Both simple and wedge osteotomy necessitate the production of a compound fracture; but in the former the operation is almost subcutaneous, and in the latter there is the absence of contusion and other ordinary accompaniments of such an injury. The results may therefore be expected to be very much better, provided strict asepsis is enforced.

The procedure which I have found most effective is as follows:

On the day previous to the operation the leg should be shaved, then washed with soap and water and afterward with ether, after which it is enveloped in towels which have been dipped in sublimate solution (1–2000), and then dried. These will remain *in situ* until the patient is etherized, when the final washing with bichloride (1–1000) is made. Instruments are first to be placed in boiling water, then in carbolic acid solution (1–20). The rubber cloth should be placed on top of the sand-bag, and then covered with a single layer of wet bichloride towels. The region of the operation should be well surrounded with carbolated towels. One of the osteotomes should be both wider and thicker than the other, the latter being used in the deeper portion of the section so as to prevent wedging. I have never been unfortunate enough to break off an instrument in the bone, but this accident has occurred in the practice of experienced surgeons, and a portion of the chisel has been allowed to remain. I should prefer to loosen and remove it by cuts alongside.

The osteotome should taper gradually, not abruptly, and should be driven by light taps of the mallet after the anterior cancellous tissue has been passed, lest a splintering or a long oblique fracture be produced. Several times while rapidly demonstrating this operation to a class, I have in the cadaver made a fracture that extended obliquely for many inches. The posterior one-fourth of the bone should always be fractured manually, lest the instrument injure the artery, which, from displacement, may lie directly behind or alongside the bone. Dandridge[1] was unfortunate enough to lose a patient from pyemia, after an injury of the posterior tibial artery and vein, which both lay directly against the tibia.

1. *Linear Osteotomy.*—In simple osteotomy an Esmarch bandage is not desirable,

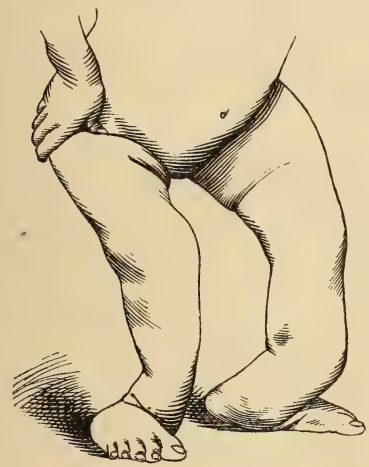

Fig. 1.

Fig. 1 shows only the lower half of the body; but in this case nearly every long bone was curved. Locomotion was impossible except with a waddling gait and with the trunk supported upon the thighs by the hands. When the patient stood, each tibia rested upon the dorsum of the foot. Both legs were "cork-screwed," and the femora bent both outward and forward. All the epiphyses were enlarged, and the elbow articulation was so distorted that the arms could be only partly flexed. Both clavicles were sharply bent forward at their centres.

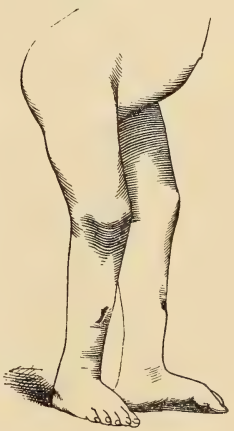

Fig. 2.

Fig. 2, from a photograph, shows the result of the osteotomies in case shown in Fig. 1.

[1] *New York Medical Journal*, 1886, xliii, p. 129.

[1] *Boston Med. and Surg. Journal*, 1885, cxiii, 25.

as the outflowing blood is of advantage in effectually preventing the entrance of air.

In regard to the cases suitable for the simple cut, experience has taught me that even where the angle has been very prominent, there is no necessity for taking out a wedge, as nature is abundantly able, provided no septic influence is introduced, to unite the bones solidly even if they were angularly placed. The incision with the knife should be directly down through the periosteum, and should be no longer than just sufficient to permit the osteotome to turn crosswise without tension. In children the fibula need not be touched, as it can be easily fractured; but in the sclerosed bones of lads or adults, a separate section will be necessary. The larger osteotome should not be removed from the bone until more than one-third of the diameter has been traversed, although it should frequently be moved sidewise to prevent wedging, and to incise different portions of the structures in large bones. The smaller instrument should be carefully inserted in the exact track of its predecessor.

An operator soon learns to distinguish the increased density of the compact tissue when the posterior region is reached, and will withdraw the osteotome before it has penetrated this layer, when fracture will readily complete the solution of continuity.

Rectification being now performed, section of the tendo Achillis is usually done with benefit, as it relieves much of the tension upon the parts, permits better adjustment and reduces the tendency to future displacement. Irrigation with sublimate solution should be frequently practised during the progress of the section, and upon the withdrawal of the instrument an aseptic sponge should at once close the wound, and remain in position.

Without waiting for hemorrhage to cease, unless it be profuse, all tissue is removed from between the edges of the wound, a few strands of cat-gut introduced, and the lips drawn together by cat-gut suture or strip of adhesive plaster—preferably the former. Irrigation should be continued until the sublimate gauze (freshly wet, in children, with 1–2000 solution) is actually in place.

I have abandoned both protective and iodoform. Dry sublimate cotton is now applied as a roller to the leg and foot and is held in position by an antiseptic or flannel bandage.

Plaster-of-Paris rollers soaked in warm salt water are now applied, the limb is extended, and the deformity slightly overcorrected, until fixation is complete. To insure accuracy of position the plaster encasement of the leg should first be completed; an assistant then rests the heel of the patient upon the thumb and finger of one hand and grasps the toes with the other, which position he must maintain during the envelopment of the foot and the setting of the plaster. As a rule, but little morphia will be required, and if no pain or odor is present, and the temperature is good, the surgeon will have little to do for four or five weeks as the case progresses to good union without suppuration.

The temperature chart is not an infallible guide as to the condition of the parts, yet it is one of the best indications; and if no evidences of suppuration exist, the dressing need not be interfered with, as disturbance of any wound, so long as it is sweet, is harmful. Should the cast become loose, it should be sawed open, the leg examined to see that good position is maintained, and the encasement drawn closer together by a bandage.

If other osteotomies are to be performed at the same operation, each fracture as it is produced should be wrapped in a sublimated towel, while a pledget of antiseptic cotton is fastened over the wound. A temporary wooden or paste-board splint should be applied, lest in the manipulations of the subsequent operations the muscles and possibly the bloodvessels should be lacerated by a sharp-pointed fragment.

2. *Cuneiform Osteotomy.*—The removal of a wedge-shaped piece from the tibia is only necessary when the angle of curvature is very great, and especially when it approaches the right angle. To determine the amount of bone necessary to be excised, one soon learns to judge with sufficient accuracy by his eye. If exactness is desired the sphenometer[1] may be used, or the anterior surface of the limb may be outlined upon a piece of stiff paper. This line paralleled by one at about the supposed antero-posterior diameter of the tibia, will give the size of this bone. When the pattern is cut out as drawn, a rude representation of the tibia will be secured which, when cut through at the point of the curvature, and straightened, will at once show the size of the wedge.

As a cuneiform section is much more serious than simple osteotomy, every aseptic precaution should be used to prevent suppuration. These have already been enumerated. The application of a sterilized

[1] *Therapeutic Gazette*, 1887, p. 154.

Esmarch bandage assists greatly in the proper formation of the wedge, by giving a good view of the cut bone surfaces. A chisel, beveled upon one side, is used instead of an osteotome.

If rigid, and in large children, the fibula should be first divided, but the removal of a wedge from this bone is never necessary. The knife incision over the tibia should be a little larger than the proposed base of the wedge, and the periosteum should be cut not only longitudinally but also laterally, in order that it may be preserved intact without laceration, and that it may be subsequently sutured.

The wedge is not taken away entire, but is made rather by a series of chippings until the proper amount is removed.

The posterior portion of the bone is fractured by manual force as in simple osteotomy. If the instrument is driven too rapidly, or carried too deeply into the bone, a very oblique fracture may result. Tenotomy of the tendo Achillis should always be performed if there is any restraint against rectification.

Many surgeons fasten the ends of the bones with wire,[1] silkworm-gut, kangaroo-tendon, etc.; but I see no necessity in the majority of cases for the delay and for the additional incentive to suppuration. In angular malunion following fracture, however, I always use the inter-osseous suture, as there is ordinarily a tendency to non-union. Upon the removal of the Esmarch bandage the hemorrhage will be very free from the cut surfaces, but hot water or eburnation will usually arrest it. Stuffing the wound with alum gauze is rarely if ever necessary, and if it is used the material should be removed within twenty-four hours. Drainage, while unnecessary in simple osteotomy in which organization of blood-clot will occur, is here of the greatest importance for the prevention of suppuration.

All fragments of bone should be thoroughly removed by irrigation (with 1 to 2000 sublimate solution, in children), and the ends brought closely together *without any pinching of tissues*. A failure to observe this rule will ensure defeat, as will also the retention of any tissue in the lips of the wound when it is closed by cat-gut sutures. Either sterilized horse-hair or cat-gut may be used for drainage; I prefer the former.

When there is an opening at the fibula a roll of horse-hairs is carried into the tibial wound with a pair of forceps, and made to emerge at the opening of the former; another small bundle is carried directly through from the bottom of the wound to the posterior aspect of the leg through a counter opening. Cat-gut may be allowed to remain permanently, although I prefer to take it away, as I do the hair, in thirty-six hours.

In applying the dressings, the same thorough precautions are necessary to obtain asepsis until the moment that the wound is covered with gauze. The sublimate cotton, plaster bandage, etc., are applied as before, except that the latter is put on as a recurrent longitudinally along the sides of the limb at the seat of operation, in order to give additional strength laterally. In front and behind, at the site of the proposed windows, the cast is made thinner and the ends of the horse-hairs arranged so that they can be withdrawn without interference with the remainder of the dressing.

A slight over-correction of the deformity is advisable while the plaster is setting, and extension should also be made in order to secure good apposition of the fragments. When windows are cut in the cast on the second day, the staining of dressings with blood does not necessitate their removal so long as decomposition has not taken place. A moderate wetting with sublimate solution after the withdrawal of the drain will prevent all odor for a week or ten days, when union of the soft parts will have occurred, and a fresh dressing may be applied through the opening. Care should be taken that pressure should be accurately made upon the tissues beneath the window, lest local œdema and pain ensue. Usually these cases go on to speedy and perfect union. Occasionally, through some fault in the operation or in the dressing, suppuration ensues, in which case the cast about the opening should be coated with shellac, the wound thoroughly washed and antiseptically dressed, when the cessation of pus formation may be soon secured.

In the case from which the accompanying figures were prepared, while one limb healed kindly, the other suppurated, and several particles of bone were discharged; nevertheless, a perfect union and a good leg resulted.

I have never ventured beyond six osteotomies at one time, but as high as ten have been performed.[1] It is my custom to

[1] *St. Bartholomew Hospital Reports*, 1886, xxii, 40; also 1884, vol. xx, p. 59.

[1] *Dublin Jour. Med. Science*, vol. LXXIX, p. 292; MacEwen, Trans. Eighth International Medical Congress, Copenhagen, 1884.

rectify coexistent knock-knee by a simultaneous supra-condyloid osteotomy, Figs. 3 and 4; but I have always left the high curve which so often exists in the femur, intending to do section later. Thus far, however, all my cases have been so greatly improved in locomotive powers that I have hesitated to incur the possible risk of rotation of fragments or of placing the head of the femur after reunion in a new relation to the acetabulum; and have also reasoned that as both pelvic and thigh muscles had for years accommodated themselves to the abnormal positions, more or less disability might occur by throwing them into new mechanical relations.

All my sections at the upper end of the femur have been for hip-joint anchylosis, and in cases in which I did not expect to secure the proper apposition of femoral head and acetabulum, since both had been either greatly altered or already destroyed.

Fig. 3.

Double knock-knee with double anterior curves.

B.—*Section with the Saw.*—Several very oblique fractures which have recently been produced by me in making sections of the bones by the osteotome and chisel, in which very sharp ends of fragments have rendered injury of the soft parts and blood-vessels imminent, have led me to look favorably upon the operation with the saw. I have never practised it upon the leg bones, although frequently employing the saw on other bones. The section could be performed almost absolutely subcutaneously, and I have never had suppuration follow its use in other cases. The saw should be blunt pointed, should have a short cutting face, and the puncture with the knife should be only just large enough to admit the saw. Care should be exercised that neither blood-vessels nor nerves are injured.

Will the deformity return? Doubtless, if too early locomotion is attempted without support, or if a febrile or other exhaustive disease speedily follows the operation. Such a softening of the callus before it is thoroughly ossified is possible after any fracture; but is rare. Should it accidentally occur, the case should be treated as one of mal-union or of delayed union; *i. e.*, first, by reposition and fixation with gypsum; then, secondly, by open osteotomy and wiring of fragments, with long-continued subsequent support.

Conclusions.—1. Anterior tibial curves during the soft and springy stages may be corrected by manual rectification and the use of apparatus.

Fig. 4.

After osteotomy.

2. Braces are useless after hardening has occurred.

3. Manual fracture is the best and safest remedial operation in young children.

4. Instrumental fracture, or osteoclasis, is not as safe or effective as osteotomy.

5. Aseptic simple osteotomy, for all moderate degrees of curve, and cuneiform section for very severe grades, give almost uniformly good and speedy results, without suppuration. Subcutaneous section by the saw is also a reliable operation.

6. Plaster of Paris is the simplest and most effective material for securing accurate position and maintaining absolute fixation. By its use the delay and injury incident to suturing the ends of the bones is avoided.

1818 Chestnut St.

TUBERCULAR MENINGITIS.[1]

BY T. J. HAPPEL, A.M., M.D.,
TRENTON, TENN.
PRESIDENT OF THE TENNESSEE STATE MEDICAL SOCIETY.

Tubercular meningitis is one of the most fatal of diseases. I do not refer in this statement to the total number of deaths from it, but to the fact that there are very few recoveries when the victim is once seized with it.

Definition.—The name itself defines the disease. By tubercular meningitis is meant an inflammation of the meninges, usually at the base of the brain, due to the deposit in these membranes of tuberculous material. The presence of tubercles in the meninges, and inflammation arising therefrom, is the "*sine qua non*" of tubercular meningitis. Post-mortem examination may reveal tubercular deposits throughout the system, as well as in the meninges. In the meninges, we find miliary tubercles—grayish white granules, varying in size from a minute speck to that of a pin-head, which in the aggregate may make a mass as large as a pea. These tubercles are very unevenly distributed, being most commonly found in the pia mater at the base of the brain, though at the same time they are often met with in other locations. The amount of inflammation does not depend upon the number of tubercles.

Etiology.—The causes of the disease may be divided into predisposing and exciting. Among the predisposing causes may be classed any and every thing that tends in any way to impair vitality. Heredity, therefore, becomes a strong predisposing factor. Tuberculosis, scrofula, the so-called scrofulous diathesis, and syphilis are chief among the diseases which when transmitted by either parent to the child may implant in the offspring such a condition of malnutrition as may lead to the production of a state of the body favorable to the development and growth of tubercles. I emphasize the three diseases above named, as I shall have occasion later on in this paper to refer to them again. The eruptive fevers, and whooping-cough in young children, may also be classed as predisposing causes, because in many cases, children, after attacks of those diseases, are left feeble and weak—almost in a condition of marasmus—furnishing pabulum just suited to tubercular deposits and growths.

[1] Read before the Gibson County Medical Society, September, 1888.

Age can be cited as another predisposing cause. We find the disease oftenest in children between two and seven years of age; and next in frequency in young adults, between twenty and thirty years of age. Marriage in close consanguinity, by tending to weaken the offspring of such unions, favors the development of tubercular meningitis. Children of a scrofulous diathesis, however it may have been acquired, and children in whom the nervous system has been developed at the expense of the muscular, are predisposed to the disease. Precocious children, with a pale, flabby skin, soft, relaxed muscles, blue eyes, with a mature general appearance, are prone to the development of the disease. In some cases, however, no predisposing cause can be discovered. One child in a whole family may have the disease, and all the rest, as well as the parents, remain healthy.

Among the exciting causes may be classed, first of all, poor hygienic surroundings. Bad, scanty, and improperly cooked food, close confinement in tenements, and such like influences, as well as sudden changes in temperature, exposure to cold, etc., act as important exciting causes. Hence we find the disease more common among the poor in cities than we do in the country and among the rich; though the latter are by no means exempt. Improper feeding of children, where there is any tendency to tubercle, especially hereditary, is liable to develop tubercular meningitis. Caries may act as an exciting cause; so also may the presence of caseous material anywhere in the system. In many cases, no exciting cause can be discovered. The latest, newest, and therefore the most commonly accepted cause of tubercular meningitis, is a specific cause, the *bacillus tuberculosis*. The disposition of late is to trace all diseases to some micro-organism, animal or vegetable, and we find the disease in question no exception. It is contended that wherever tubercle exists, especially in the lungs, this bacillus can always be found and its presence in the sputum of the patient demonstrated with a powerful microscope, and that it can be differentiated by staining with a strong solution of carbolic fuchsine, which imparts a red color to the bacillus, and then by making "the contrast staining by what is known as Fraenkel's solution, the specific bacillus remaining a deep red, and the other elements in the sputum blue." In my own opinion, this bacillus has not been positively shown to be the cause of the disease, but is more probably a sequence.

Proper pabulum for its development is furnished in systems enfeebled as above described, and the bacillus finds its nidus in this prepared soil and there grows.

The symptoms of the disease may be divided into those pertaining to two periods: the prodromic, and the stage of invasion. The prodromic stage corresponds to and represents the period of the deposit of miliary tubercles, or, as believers in a specific bacillus would say, the time elapsing between the date of the reception of the bacillus into the system, and its multiplication and fixation in sufficient numbers in the pia-mater at the base of the brain to give rise to irritation. This period is of variable duration, from a few days to weeks or perhaps months. During this time changes are noted in the general disposition of the child and in its conduct. The disease rarely appearing before the second year, these changes can be easily noted and studied. As remarked previously, the victims of this disease are usually bright precocious children abounding in life. From being always playful, the child becomes dull and listless, at times apathetic, fretful, peevish, irritable. He cannot be interested long at a time in any way. Whilst playing, he suddenly stops, and wants to be taken up. He becomes a different child in every respect. But the most marked change is in the loss of flesh. The child becomes pale, and his flesh loose, flabby, and progressively diminishes. His features take on an old look. There is a vacant stare about him. His appetite diminishes and he occasionally vomits. He complains at times in a vague way of his head. At night, in his sleep, he is restless, tossing from side to side in his bed, and frequently groaning, and grinding his teeth. According to Pepper, young children often "manifest a strange perversity, or an unusual disobedience, for which they may be punished under the belief that it is intentional." Whilst the foregoing are some of the chief symptoms of the disease in children, they may vary from being so slight as to be overlooked, to being most severe.

The symptoms of the stage of invasion may be subdivided into those of irritation, pressure, and collapse. It is difficult to mark the transition from the prodromic stage to that of irritation. The change is so gradual that it is impossible to say just where one ends, and the other begins. The chief distinguishing feature of this period is the occurrence of fever. The prodromic stage is ordinarily attended by no fever, but in the stage of invasion the temperature rises to 103°, or in some cases higher, though generally lower. The pupils are unequally dilated, and sometimes strabismus is present. Headache increases. There is sensitiveness to light and sound, and sometimes twitching of the muscles. In a few cases violent convulsions occur. The pulse rate in this stage is usually slow, though, exceptionally, it is frequent. The respiration is slow and irregular, and the tongue coated. The bowels are constipated, and the abdominal walls retracted, and vomiting is a prominent symptom. The little patient at times lies in a stupid, comatose condition, from which he arouses with a sharp shrill cry—the hydrocephalic cry. During sleep, delirium is a prominent symptom. There is intolerance of light, the little patient frequently trying to shut out the light by burrowing the head down into the pillows. His somnolence becomes more marked in the latter part of this stage, though he can be roused, and will answer questions rationally, after which he lapses almost at once into a condition of half-sleep. He gradually becomes less and less irritable, allowing examinations to be made without resistance of any kind. The eyes become dull, the cornea takes on a lustreless appearance. Somnolence deepens still more, and it becomes next to impossible to rouse him.

In this stage of the disease symptoms of apparent improvement may occur. The parents flatter themselves that convalescence is about to set in. All symptoms appear better; but these hopes are soon blasted. The duration of the stage of irritation is from a few days to a week. The transition from this to that of effusion with depression, is not marked except by the gradual deepening of all the foregoing symptoms. The pupils are unequal and respond slowly, if at all, to the light. The muscles of the back of the neck become stiff, and occasionally opisthotonos occurs. The bowels are constipated, and the urine is retained or is passed involuntarily. Deglutition becomes difficult; the appetite is completely lost. The respiration is irregular and sighing—the Cheyne-Stokes form being common. The temperature in children is frequently subnormal, even when there are convulsions. The pulse is slow, irregular, and intermittent, the irregularity being a marked feature. The sudden vomiting ceases. The child at times interrupts this condition

of stupor by convulsions, and by giving utterance to the peculiar, sharp, hydrocephalic cry. According to Prof. Loomis, "the ophthalmoscope reveals varicosities of the retinal veins, points of hemorrhage . . . and white, miliary granulations on the retina and choroid." As in the first stage, so in this, there are cases of apparent improvement or even recovery, but in a few hours the child rapidly lapses into a more stupid condition than before. In the stage of collapse, all the symptoms point to a speedy dissolution. The whole system may become relaxed. The paralyses, which up to this point may have been transient, now become permanent. The child is bathed in a cold, sticky perspiration. The pulse becomes very frequent and feeble, varying from 120 to 200 a minute, the heart being released from the inhibitory influence of the *par vagum*. The respiration sympathizes, and becomes frequent, but sighing and very irregular. The pupils are widely dilated. The eyes are rolled upward, showing but little of the cornea, and are insensible to light. The abdomen becomes tympanitic. Involuntary discharges from the bladder and rectum take place. Subsultus is marked. Coma deepens, and death may take place quietly and gradually during this condition, or it may occur from asphyxia in the midst of a convulsion. This stage usually lasts from twenty-four to forty-eight hours, though very rarely the child may linger for an indefinite time in this state of living death.

I have not referred to the condition of the fontanelles in this disease, as it rarely occurs before they have closed; but in the stage of invasion in very young children they are prominent from distention of the brain with the hydrocephalic fluid, whilst in the state of collapse they are depressed.

There are some distinctive features of this disease which should be carefully studied, in order to diagnosticate it promptly when it is met with. The premonitory stage presents usually a frequent pulse, with possibly some little irregularity; the respiration is normal and the temperature almost normal. There is loss of flesh, and vomiting. In the irritative stage of invasion, the pulse and respiration become slow and irregular, the latter frequently sighing. The temperature begins to rise, rising and falling irregularly, though rarely going above 103°. It varies many times each day, but the evening temperature averages a little higher than the morning. Loss of flesh continues, so also does the vomiting. In this stage of the disease, in the majority of cases, the *tache cérébrale* is found—the red mark responding promptly to pressure of the finger on the face; but general flushes alternating with pallor are met with in nearly all cases.

In the stage of collapse, the pulse and respiration become rapid and more irregular. The Cheyne-Stokes respiration marks the last stage of the disease. The temperature may sometimes rise till just before death, and then it falls rapidly. The peculiarities of circulation and respiration are very easily understood and explained by remembering the fact that both are controlled by the *par vagum*, and that in the prodromic period the disturbance of the roots of the nerve and the medulla oblongata is irregular, producing a frequent, varying pulse and respiration; but in the first and second stages of invasion, the irritation is continuous and the inhibitory function of the nerve is kept in play, so that both acts are restrained, whilst in the stage of collapse, in the resulting paralysis, the nerve loses all controlling power and both respiration and pulsation are quickened and made irregular. In an analysis of fifty-six consecutive cases, reported by Dr. Wortmann (*Jahrbuch für Kinderheilkunde*, 1884) "retraction of the head was present in all but one case, and commenced when the pulse became irregular." The temperature never rose above 104°. Hyperæsthesia was present in all but one case where the spinal meninges were involved. Vomiting was one of the most characteristic symptoms, and was considered a diagnostic one when it occurred from a comparatively empty stomach and without effort. When food was present, it seemed to be almost a regurgitation of the ingesta.

The duration of the disease, after the prodromic period, ranges on an average from two to two and a half weeks; but in some few cases the disease has terminated abruptly in a few days. Many circumstances may aid in bringing about a rapidly fatal result. Those cases in which heredity can be traced are more apt to run a rapid course.

Tubercular meningitis is to be distinguished from typhoid fever, which also has a prodromic period, by the fact that epistaxis is very rare in tubercular meningitis; that in typhoid fever the temperature is more regular, and the pulse grows progressively more rapid, whilst in tubercular meningitis it is first rapid, then slow, then rapid again. Again in typhoid fever the abdomen is, early in the disease, tympanitic and tender, with a tendency to too

frequent evacuations from the bowels, whilst in the disease we are considering, up to the stage of collapse, the abdomen is retracted, while there is no tympanites and no tenderness, and constipation is a marked symptom. Vomiting is a prominent symptom in tubercular meningitis, whilst in typhoid fever it is not marked, or it is absent. The acute pain in the head differs in this disease from the dull, heavy headache in typhoid fever. Finally, tubercular meningitis most often occurs in children under six years of age, whilst typhoid fever rarely does. In adults, it would be necessary to keep in mind the whole history of the attack to make a certain diagnosis.

From remittent fever of children, the diagnosis is made by the fact that in the latter disease there are usually no prodromic symptoms, the invasion being abrupt. Whilst there may be vomiting, it is not a marked symptom of the disease. The coated tongue, aching head and back, the enlarged spleen and liver, with the regular rise and fall of temperature, are symptoms distinctive of remittent fever. Especially does the temperature aid much in making the diagnosis. In tubercular meningitis the temperature rarely exceeds 103°; whilst in remittent fever, it frequently reaches 105°, falling during the day to about 100°, these variations taking place regularly, and not as they do in tubercular meningitis. The pulse in remittent fever is quick and full throughout, and frequent in direct proportion to the temperature; whilst in tubercular meningitis it is, up to the period of collapse, slow, feeble, and irregular, frequently intermitting.

From cerebro-spinal meningitis the diagnosis can be made by remembering that in this disease there are no prodromic symptoms. The invasion is sudden and without warning. All of the symptoms are more grave at the very onset. The temperature at first is higher and the pulse more frequent. Cerebro-spinal meningitis in fatal cases does its work quickly. Headache, pyrexia, convulsions in children, and active delirium, are present early in the disease. Unconsciousness ensues in a few days, and the duration of the disease does not usually exceed a week. There are a number of other diseases from which it might be necessary to distinguish tubercular meningitis; but, while none of the symptoms of tubercular meningitis are pathognomonic, yet when grouped together they afford ready means of making a diagnosis.

The prognosis is fatal. There have been a few so-called cases of tubercular meningitis cured; but when careful investigation is made of the history of these cases, the conclusion reached is that they were not cases of tubercular meningitis. Dr. de Gassicourt concludes that most of the alleged cures are "examples of meningitis of a limited extent arising from tubercular tumors, syphilitic gummata, cerebral scleroses, and neoplasms of various kinds." Loomis says: "Tubercular meningitis is one of the most fatal diseases of childhood." Many authors state that it is always fatal after its characteristic symptoms are developed. Watson claims that there is some chance of saving life, if "the complaint, or tendency to the complaint, is detected early." He cites authorities to prove the cure of some cases. He refers to 76 cases, with 19 recoveries. He closes by saying: "I must confess my own suspicion, that they were, most of them at least, cases of what I have called simple encephalitis." Bartholow says: "Although a very few cases have been reported cured, it is held to be an incurable disease, and the termination fatal."

To the same purport, I might quote Flint, Wood, and others. The German writers are the only ones who claim cures. All my own cases have proved fatal.

The only rational treatment is prophylactic. The surest prophylaxis that could possibly be adopted would be to prevent the begetting of children of a scrofulous or tubercular diathesis. It is wrong, and ought to be made a punishable offense in some way, for persons known to be scrofulous or tuberculous to marry, *especially* to *intermarry*. The offspring of such unions, in far the majority of cases, will be diseased. The "survival of the fittest" in such cases should be substituted for the preservation of the fittest. Syphilis in many cases bears the same relation to tubercular meningitis that scrofula does, and needs to some extent similar legislation. Persons having contracted syphilis should not be allowed to marry before the expiration of not less than three years from the date of the development of the disease, and then only when there exists no trace of the disease. I do not pretend to argue the question of the transmission of the tubercular diathesis as a result of such unions; this fact is admitted by all of the best authorities of the present day. In my opinion, close consanguineous marriages should be forbidden by law. No raiser of fine stock will breed "in and in." The strains of blood must

be crossed. He recognizes the fact that the "in and in" breeding produces, as a rule, feeble, delicate, deformed, short-lived offspring; hence such breeding is not done on the best stock farms. If the rule holds good in reference to horses and cows, much more should it hold good in reference to the human family, animals of finer mechanism and more to be guarded. I find on page 339 of "Medical Statistics of the Provost-Marshal General's Bureau," the following statement in reference to a family near Altoona, Pa.: There were "two families of Scotch-Irish birth located there, who were intelligent, healthy, thorough-going people, possessing strong vitality and great endurance. Their children commenced marrying and intermarrying, until now, in the fourth and fifth generations, there is not really a sound adult known in all their extensive connection, proving as far as it goes, the evils of the intermarriage of relatives." In Pepper's System we read as follows: "Consanguineous marriages have been time out of mind held to be very objectionable. . . . My own conclusion is . . . reproduction is most normal, and gives best results when a considerable genetic difference (within the limits of species) exists between parents. . . . Moreover, so few families possess an absolutely faultless health-record, that the chances of increasing existing morbid traits by intermarriages are quite sufficient to justify the commonly held objection against them." It is an admitted fact that everything that tends to deteriorate the vital powers, to that extent aids in producing a tuberculous diathesis, and that when this diathesis exists, then we may have in the children tubercular meningitis. I could cite many authorities to show the injurious effect of consanguinity in the marriage relation. My own observation teaches the same. If I were asked to say where the line should be drawn, I would answer that there should be no intermarrying where the blood relationship was closer than that existing between those in common parlance called "third cousins." Confirmed drunkards should not be allowed to marry, because in many cases the children resulting from such unions are epileptics, or have other cerebral or nervous disorders, besides a general feebleness of constitution.

In the next place, where we have these children inheriting a tuberculous diathesis, what can be done to prevent tubercular meningitis? They should be kept much in the open air, where they can bask in the sun's rays; should be supplied with plenty of nutritious, wholesome, well-cooked food; and should be well clothed so as to be protected against sudden changes of temperature. Sedentary amusements should be prohibited as much as possible. School hours for such children should be short. School-rooms, where they attend school, should be well ventilated and the temperature kept uniform, and light should be abundant. They should sleep in well-aired bed-chambers, so that there could be no possible doubt of an abundant supply of pure air at night. They should be bathed daily in cold or tepid water, according to the age of the child or the season of the year. The bowels should be kept regular and open. Cod-liver oil should be administered freely—the more the better—up to the point of toleration. Iron, either in the form of the syrup of the iodide, of the potassio-tartrate, should be prescribed. Visits to the seashore, or some general change of air, should be made once a year at least. Whenever it can possibly be done, all of the children born of such unions as would be expected to produce feeble, delicate offspring, should be cared for as just pointed out.

When tubercular meningitis has once fully begun, since nothing can be done to arrest its progress, all the symptoms should be met as they arise. In the early stage of the disease, the nervous restlessness and irritability must be met with sodium or potassium bromide in full doses. Sometimes it will be necessary to add chloral to induce sleep. If the pain in the head is great, the ice-cap may be applied to relieve it; should that fail, opium in some form will be needed. The bowels should be kept open, but active purgation should be avoided. Liquid diet should be freely given. In the stage of effusion, iodide of potassium will be necessary; shaving the head and anointing it with an ointment of the biniodide of mercury may be resorted to. The iodide of potassium should be given in dose of two grains every four hours to a child three years old, and the ointment should be rubbed on, morning and night. After any treatment patients with tubercular meningitis die—at least that has been my experience with the few cases which have come under my experience. We should, however, prescribe suitable remedies, because it may be possible that simple meningitis (cerebro-spinal) may have been mistaken for tubercular.

In conclusion, I would impress upon you the thought that an early diagnosis should be made, and that the parents of the child should be candidly informed of the hopelessness of the case.

A CASE OF ENCEPHALOCELE.

BY D. A. HENGST, M.D.,
PITTSBURGH, PA.

On September 24, 1888, I was called to attend Mrs. James G., 22 years old, in her second confinement. On my arrival at the house I found that the child had been born for several minutes, and that the labor presented nothing unusual and had lasted only about one hour. On examination it was found that the child had what, upon a superficial examination, seemed to be a large hernial tumor protruding from the posterior part of the cranium; this tumor was larger than the head of the child, and was covered with hair around its circumference for about one-third of its extent, the covering consisting of a continuation or stretching of the scalp. It was of a soft, doughy feeling, and slightly discolored in several places. The head of the child was almost flat from the eyebrows backward, and consequently appeared much smaller than the ordinary fœtal head at full time.

The child, which was a male, had no other malformations, was of the ordinary size and well developed in all its parts. The presentation had evidently been by the vertex position, as the woman who was present stated that the tumor appeared first at the vulva; the mass being soft and the head otherwise small made the delivery quite easy. The child lived three days, death being apparently due to starvation. It had made no effort to nurse at the breast and it would not swallow when artificial feeding was attempted; it could open its eyes and cried lustily several times.

On *post-mortem* examination made twelve hours after death, the tumor was found to make its exit from what seemed to be the posterior fontanelle, which was greatly enlarged; the anterior fontanelle was absent and the sutures united by cartilage, so that the entire cranium seemed to be one. About three-fourths of the cerebrum was found within the tumor, and it was highly injected; the part of the cerebrum remaining within the cranium was normal in its appearance. The membranes of the brain were normal in appearance and covered the entire mass. The cerebellum was entirely absent, the growth having apparently originated from and underneath the tentorium cerebelli. The cerebral ventricles were found within the tumor and in a normal condition; the sac also contained about four ounces of serum, no communication existing between the ventricles and the serous fluid, as is commonly found in these cases. In this kind of labor there should be no difficulty in the delivery of the child, inasmuch as the tumor was soft and the bony parts of the head small.

On first examination the tumor might be mistaken for a second head, and podalic version performed, as in a case reported by Tarnier. Should the child present by the breech and delay occur in the delivery of the aftercoming head, the obstacle to

delivery might be overcome by puncturing the head. These cases are exceedingly rare and very interesting; in an obstetric practice of nearly one thousand cases this was my first of the kind.

The accompanying wood-cut, made from a photograph taken thirty-six hours after the birth of the child, will serve to illustrate the size and appearance of the deformity.

3600 Fifth Ave.

—The *Popular Science News*, Jan., says that the body of a boy drowned at Winchendon, Mass., recently, was found through the use of the electric light, a bulb being fastened to a pole and submerged, illuminating the water for a considerable distance in the neighborhood. The electric light promises to become an important aid in all manner of submarine operations.

SUB-SPINOUS LUXATION OF THE HUMERUS; REPORT OF A CASE.

BY B. BRABSON CATES, M.D. (Univ. Pa.),
MARYVILLE, TENNESSEE.

Whilst sub-glenoid, sub-coracoid and sub-clavicular luxation of the head of the humerus are met with in the practice of almost every physician, systematic writers such as Agnew, Ashhurst, Gross, Erichsen and others are agreed that the backward or sub-spinous dislocation of the head of the humerus is a very rare occurrence; there being, according to Ashhurst, only twenty or thirty cases recorded in the literature of surgery.

Without following compiled statistics, showing the relative frequency with which various parts are dislocated, I trust the report of the following case will merit the attention of the profession.

Mrs. A. White, married, 58 years old, was out driving with her little granddaughter on July 18, 1888, when her horse became frightened and ran away with her. The buggy was dashed against a tree and overturned. In the effort to save her little grandchild from injury, Mrs. A. was thrown forward, striking on her right elbow and on her right shoulder. She was also struck on her head and was rendered unconscious for some time. When first seen by my friend Dr. B. A. Morton she had somewhat recovered from shock, and was able to answer questions. Dr. Morton made her as comfortable as the surroundings would permit and had her taken to her home, where I saw the patient in consultation with him.

When I first saw her she was suffering great pain. On examination I found an ugly gash over the olecranon process of the right elbow, and the shoulder of the right side was very much swollen and contused, and very tender on pressure. She complained bitterly of any attempts to move the arm. I noticed a round tumor beneath the spinous process of the right scapula, which on palpation was firm and unyielding. By pressing my hand firmly into the axilla of the same side and rotating the arm I could not elicit any movements from the head of the humerus, but, on the other hand, I could see the round tumor move beneath the spinous process of the scapula. No other injuries, beyond those of the head, shoulder and elbow, were received.

Dr. Morton and I agreed that our patient had sustained a sub-spinous dislocation of the right humerus, which we set to work to reduce. We reduced the dislocation by extension, and counter-extension, and pressure from behind. I then bound the arm in the Velpeau position, and ordered evaporating lotions to be applied to the injured parts to allay the inflammation and to reduce the swelling; and also ordered morphine to relieve the pain.

A NEW METHOD OF DIAGNOSIS IN OBSCURE CASES OF ENTERO-VESICAL FISTULA—SENN'S HYDROGEN GAS TEST.

BY CHARLES P. NOBLE, M.D.,
SENIOR ASSISTANT PHYSICIAN TO THE PHILADELPHIA LYING-IN CHARITY.

I was recently asked by Dr. Charles Meigs Wilson, physician in charge of the Philadelphia Lying-in Charity, to see a patient of the institution, supposed to be suffering from fistula. It is not my purpose to report the case in full. Briefly, the woman had what was called an ischio-rectal abscess about five years before she entered the hospital. Some time after this abscess discharged she states that she began to pass, at irregular intervals, wind and small pieces of fecal matter *per urethram*. No symptoms of bladder irritation exist. An extensive cicatrix, following ulceration produced by a pessary, is present in the vagina. It extends along both sides of the vagina and across the posterior fornix (behind the cervix). In view of the absence of bladder irritation, and of the well-known ignorance of anatomy exhibited by the laity, it was thought likely that if the fistula did exist it was a recto-vaginal fistula. A careful examination under anæsthesia by touch and sight made by Drs. Wilson, Hawley, myself and others, failed to demonstrate the existence of any fistula communicating with the vagina. But two conclusions could be drawn; either the patient was right, or else she was a malingerer. The last seemed probable from what was known of her. It was suggested that a careful and extended study of the urine made with the microscope might determine the diagnosis—particles of vegetable fibre, or the seed of small fruits might be found. This plan involved much labor and time.

It occurred to me that the hydrogen gas test would settle the matter quickly and positively, and I suggested that it be employed. The recommendation was accepted and the following day Dr. Wilson forced the gas into the rectum and lighted the gas at the end of a catheter introduced into the

bladder. I could not be present at the time, but Dr. Wilson told me that no gurgling sound was heard (caused by gas passing the ileo-cæcal valve), hence it seems plain that communication exists between the bladder and large intestine.

I offer this as a new and valuable method of diagnosis in obscure cases of entero-vesical fistula; or, if you choose, a new application of Senn's hydrogen gas test.

Society Reports.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT, SECTION FOR SURGERY.

Stated Meeting, January 2, 1888.

The President, Edward H. Bradford, M.D., in the chair.

The Treatment of Cleft-Palate.

G. F. Grant, D.D.S., and H. A. Baker, D.D.S., presented the subject of the treatment of cleft-palate, and spoke of the use of artificial appliances in the treatment of the deformity, and exhibited apparatus and patients wearing it. The value of surgical interference was discussed by Charles B. Porter, M.D., and J. Collins Warren, M.D.

Dr. G. F. Grant referred to an experience of 21 years in the treatment of fissures of the palate by means of mechanical appliances, commencing just after the appearance of a paper in 1867 by William Suersen, of Berlin. For several reasons the results of surgical interference have been unsatisfactory: (1) because there is no union of the divided hard palate even under the most favorable conditions; (2) because there is not so much improvement in speech as was expected; and (3) because there is an increased difficulty in the adjustment of mechanical appliances afterward.

In 1873 and 1874 the surgeons of Boston—Bigelow, Warren, Hodges and Cabot—were giving attention to this subject, which they discarded later. It was about this time that Dr. Grant had his first success with a mechanical appliance After the introduction of the plate, there was at once a noticeable improvement in the speech. At first the improvement was slight, but it gradually improved for a year, when the difference was very marked. Since that time, or during the last ten years, the patient has been a teacher in one of the public schools of a large town in Massachusetts. Since 1871 Dr. Grant has treated 115 cases of congenital fissure of the palate, and the results have been such as to warrant the conclusion that there is no reasonable doubt as to the success of the appliance. The mechanism of the appliance has been urged by some as an objection, but the argument has little if any more weight than in the case of spectacles for the eyes. The cases in which adjustment is most difficult are those in which only a portion of the soft palate is absent; here the difficulty is to obtain contact of the appliance with the edge of the remaining portion of the palate. In fissures of the hard palate, on the contrary, an arched plate easily fills up the deficiency.

According to the experience of Dr. Grant, the appliance can be adjusted with success as early as the seventh year of age. It is of great importance that the hare lip, which generally accompanies the cleft palate, should be operated upon in such a way as to secure the greatest amount of mobility, because a short and inflexible lip will interfere with the articulation.

Dr. Grant exhibited a patient for whom he had adjusted an appliance several years before. The patient read from a book handed him by the Secretary of the Society, both with his appliance in position and with it removed. This test, as well as his answers to questions from members of the Society, both with and without the appliance, showed how very decidedly his speech had been improved by the appliance.

Dr. H. A. Baker said that in 1841 Dr. Stearns, a physician, made for himself the first mechanical appliance, which was adjusted and worn successfully in a case of cleft-palate. This apparatus was very complicated, having three wings, and many hinges and springs. Stearns, however, selected soft vulcanized rubber, which is not a permanent material, as it retains its value for only two and one-third or three months to a year.

In 1860, Dr. Norman W. Kingsley simplified Stearns's apparatus. He used only two wings, and he employed metal instead of wooden moulds in its construction, and thus he secured a smoother result with a better finish.

In 1867 William Suersen, of Berlin, introduced permanent materials for the construction of the appliance, thus securing a great advantage. He used hard rubber.

In 1881 Dr. Baker made his first successful appliance, and since then he has had about a hundred cases. The first apparatus was made of hard rubber and it had hinges

to aid the levator muscles in bringing it up to the posterior pharyngeal wall. The patient was 12 years of age, and the operation of staphylorraphy had been performed unsuccessfully. The Doctor considers a certain amount of training, as to the proper way of using the lips and tongue in the formation of sounds, to be essential to success after the adjustment of an appliance. In illustration, Dr. Baker exhibited several diagrams and plaster models with the appliances in position, and also two patients who showed a marked improvement in speech when wearing the apparatus.

Dr. Charles B. Porter said that he did not appear as an opponent of the views which had been advanced by the dentists; but he believed that the time has come, when it is best to review the operation of staphylorraphy, which is now so rarely performed. He would consider then:

1. Is the operation feasible and in what cases? Trelat says that it should be performed in any case unless the extent of the fissure is too great; unless previous operation has failed; or unless the parents object.

2. At what age? Dr. Porter thinks that it should be done when the child has a sufficient number of teeth to support a diaphragm, in order to keep the pressure of the tongue away from the stitches in the wound. He quoted many authorities, some of which gave the age as early as 16 months, and others at 16 years.

3. The method of operation. This should be comparatively simple. The edges should be freshened. The mucous membrane, together with the periosteum, should be freed from the bone by means of a periosteum elevator. Lateral incisions parallel to the line of union will relieve tension. Stitches should be introduced every quarter of an inch. These sutures may be either of silk or of silver wire. A diaphragm should be inserted to protect the stitches from the tongue.

4. Subsequent training in the formation of sounds is the most important of all things, and without this there can be no success attained.

Dr. Porter spoke of two cases in which he has performed the operation of staphylorraphy. In the first case, a child 14 months old, did well until about the sixth day, when the mother, in the absence of the nurse, gave the child a hard crust of bread, and the stitches were pulled out and the operation was a failure. In the second case, in a girl 16 years old, nine sutures were introduced and these were protected by a gutta-percha diaphragm. This patient did well and was exhibited. There was marked improvement in speech.

Dr. J. Collins Warren said that no operations for staphylorraphy were done previous to this century; but in the early part of the century Rue began to do the operation, and later it was done by Drs. Bigelow, John Warren, Cabot, Mason Warren and others. Dr. Mason Warren (the speaker's father) modified the method of operating, and performed a great many operations. He incised the soft parts freely, seized the uvula with a pair of long forceps, and then, having drawn it firmly across the fissure, he divided with a pair of strong curved scissors *all* of the tense tissues of the posterior pillars whether they were muscles or not. After this, the side operated on hung loose, and the same thing was then done on the other side. The edges of the fissure were then pared with a pointed double-edged knife and then the mucous membrane was separated from the parts beneath, almost as far as the alveolar processes, after which it was united by sutures. Dr. Warren performed about 100 operations. In his later operations he did not attempt to unite the fissure in its entire length, believing that the essential thing is the restoration of the arch with enough soft palate united to form a valve.

Dr. Warren exhibited the case of instruments with which his father had performed all of his operations for staphylorraphy. For sutures, he used silk which had been soaked in compound tincture of benzoin, which had the advantage that it prevented the knot from slipping. Some also claimed for it antiseptic qualities, but it is doubtful if this claim has any foundation.

Drs. Edward Reynolds and Robert W. Lovett read a paper on

Removal of Nasal Obstruction; Results in 112 Cases.

Dr. Robert W. Lovett gave the statistics of the series of cases, which were the ordinary patients that presented themselves for treatment at the Dispensary during three months in the summer. Three conditions were chiefly observed: (1) Chronic follicilitis; (2) congested mucous membrane, with abundant secretion; (3) a dry shining mucous membrane.

The treatment employed involved the destruction of the mucous membrane covering the lower turbinated bones by cauterization with chromic acid. Of the cases, 75 were subjected to this treatment;

33 were kept as check cases and only the ordinary conservative treatment by douches, etc., was employed. The history in the latter showed little if any improvement. In 5 cases there were exostoses or deviations of the septum.

Of the 75 cases in which cauterization with chromic acid was employed, 16 patients were cured; 38 were much improved; 2 were not benefited; the remainder were not heard from.

The method employed to ascertain the result after three months, was to send to each person an addressed postal card with questions to be answered and the card returned. The cards with the questions and replies were exhibited. Of the 75 cases, 16 patients were cauterized only once, and the remainder two, three, or even four times, according to the amount of the hypertrophy.

Of the check cases, two patients were cauterized after a trial without benefit of the conservative treatment for three months, with the final result of a cure.

Dr. Edward Reynolds said that the purpose of the mucous membrane of the nose is to temper the air which is going to the lungs, and thus the nose is the respiratory organ. The air always enters the lungs at a temperature of about 30° C. (86° F.), and saturated with moisture, whatever the external conditions are. The turbinated bones divide the anterior nares into three main compartments, which are normally narrow spaces, and the mucous membrane which envelops the turbinated bones is so richly supplied with blood-vessels, that it is almost an erectile tissue.

The operation which was done in these cases is simple and but little apparatus is requisite.

A six per cent. solution of cocaine is first sprayed into the nostril and then deliquesced crystals of chromic acid on a cotton applicator, made of a flattened piece of copper wire, are then applied to the whole surface of the lower turbinated bones, unless it is so large that it is best to make two applications, in which case it is first applied to the inner half. If examined with the speculum the eschar is at once seen. The application to the other nostril, if this is necessary, should be delayed from three days to a week, and the eschar should come away before a second application is made, if it be necessary. The eschar produced by chromic acid is very superficial and thus the degree of cauterization can be regulated somewhat. After the operation has been performed it is difficult or even impossible to detect any scar.

Dr. Reynolds exhibited a number of preparations of skulls that showed very nicely the swelling of the mucous membrane, the exostoses, and the deviation of the septum.

In the discussion that ensued, Dr. Vincent Y. Bowditch said that he had used chromic acid in the treatment of this class of cases for over a year in his office practice. He believes that the nose is the true respiratory organ. Some enthusiasts declare that nasal hypertrophies should be removed for everything, and thus they weaken their cause. Some even assert that asthma can be cured by this means.

Dr. Thomas A. De Blois said: The nasal hypertrophies appear both on the anterior and on the posterior ends of the turbinated bones. The hypertrophies which are anterior are the ones which are chiefly benefited by cauterizations with chromic acid. I prefer to use a round probe rather than a flat one, and I cauterize in lines only. These are made by drawing the end of the probe over the surface where it is desirable. The hypertrophies in the posterior nares are generally large, puffy masses, which shrink up a great deal after removal with the snare.

Dr. Henry L. Morse said: Many of the cases that have been reported by the speakers were patients sent by me from the Ear Department at the Dispensary to the Throat Department. I believe that a free opening through the nose is very essential in the treatment of the ear. In the case of children, nasal obstruction will increase the ingrowing of the drum of the ear, and unless the nose is taken care of, the benefit to the hearing by treatment is only temporary.

Dr. George A. Leland said: I have obtained good results from this method of treatment. There is a certain normal erectility to the mucous membrane of the nose, and hence is is not best to cauterize it too much. Dry catarrh may follow. Dr. Bosworth, of New York, applies the chromic acid by fusing a bead on the end of a silver wire. The reduction of the mucous membrane of the turbinated bones has cured the condition known as "hay fever." I saw a patient four years ago who had suffered for twenty-three consecutive years from hay fever. Not having any chromic acid with me, I curetted the mucous membrane from the lower turbinated bone. There was of course much bleeding, but there was no "hay fever" that year, nor any since.

Foreign Correspondence.

LETTER FROM BERLIN.

The New Ophthalmoscopic Examination.—Rare Pathological Specimens. — Three Dermoid Cysts. —Therapeutical Suggestions in Diphtheria.—The Latest Victim of "the Code."—German Students and their Habits.

Berlin, Dec. 21, 1888.

The new ophthalmoscopic examination advocated at a recent meeting of the *Berliner Medicinische Gesellschaft* by Dr. Bellarminow, of St. Petersburg, has attracted universal interest among the profession; regarding its scientific value and practical utility, however, considerable difference of opinion seems to exist. Your correspondent has interviewed the two greatest ophthalmological authorities in Berlin, Profs. Hirschberg and Schweigger, on the subject in question, and has found to his surprise a very different estimation of Bellarminow's method. Prof. Hirschberg said that "the same method, or one strikingly similar to it," had been described by him in 1882, in the *Archive* of Du Bois Raymond (p. 501). The method then published had reference only to the eye of fish, the pike in particular. As cocaine was not yet known Prof. Hirschberg said he had no great confidence in the new method, and did not expect any great advantages from its application. Prof. Schweigger, on the contrary, spoke rather warmly of the new method, and emphasized especially its ease of application. He stated that he had used the method repeatedly and was prepared to recommend it.

As some of the readers of the Reporter may not yet be familiar with Bellarminow's method it will not be amiss briefly to enunciate its principles. The cornea is first anæsthetized with a two per cent. solution of cocaine, and a plain glass plate is then brought into contact with and gently pressed against it. The moisture of the cornea will by capillary action develop a layer of fluid between the glass plate and the cornea, and the curvature of the latter in this way will be obliterated—two parallel surfaces being substituted for the convex lens, the normal cornea. In other words, a thin glass plate is pressed on the cocainized cornea and a high grade of hypermetropia is produced, and, consequently, an enlargement of the ophthalmoscopic field. The simplicity and ease of application of the new method are evidently its chief advantages, but it is questionable if delicate structural changes can be observed by its use. The new method will recommend itself to beginners, and for purposes of demonstration, as an examination of the eye may be made through its use by two or three persons at the same time. It may be of interest to mention that Bellarminow's principle has been practically utilized by the Fick contraction-spectacles, which consist of a glass plate ground in accordance with the curvature of the cornea and placed on the latter. The slight interval between the plate and the cornea is filled out by a drop of fluid, which eliminates the influence of the irregular curvature of the cornea.

Berlin is justly termed the pathological centre, for nowhere is pathology cultivated to the same extent as here. The focus of all pathological work is, of course, the *Patologisches Institut*, an integral portion of the Royal Charité, and presided over by Virchow. The collection of pathological specimens in the Institute is a truly grand one, and is supposed to be unsurpassed by any in the world. The latest additions to this collection were made by Virchow last week, and consist of a kidney showing deposits of lime as a result of poisoning with cyanide of mercury. These deposits can be seen with the naked eye in very fine sections on favorable illumination. Microscopically, of course, the lime deposits are very distinctly visible. Another recent addition to the collection is a very rare specimen of idiopathic perichondritis of the arytenoid cartilages. Hitherto it has been usually believed that purulent perichondritis of these cartilages was traceable always to typhoid, syphilitic, or to tubercular infection. The idiopathic nature of the perichondritis in the specimen in question was well established. Dr. Bramann, assistant of Prof. Bergmann, has recently enriched the collection by four dermoid cysts of the nose, which were all taken out by himself. One cyst was from a child four months old.

Dr. Rieck's proposal to treat diphtheria with yeast, though theoretically interesting, will find but little appreciation with the practitioner of medicine. Rieck's treatment is based on the fact that the gastric contents in diphtheria, just as in cholera, scarlet fever and measles is always alkaline. The yeast-cells—cerevisiæ—proliferate only in a neutral or slightly alkaline soil, which at the same time contains sugar. They furnish carbonic, acetic and lactic acids. The latter acid has been extensively used in the treatment of diphtheria, though

rarely ever in quantity sufficient to acidify the gastric contents. If lactic acid is pushed that far the proliferation of the yeast-cells stops simultaneously with the reduction power of the micro-organisms, and recovery takes place. The proposal is, in other words, an attempt to combat the specific diphtheria-germs with proliferating heterogenous cells—a fight between bacillus and cell on a common soil, the blood. The method constitutes, therefore, an experiment the reverse of a pure culture.

Another suggestion regarding the treatment of diphtheria, made by Dr. Gaucher, of Paris, to cauterize the deposits with the Paquelin cautery, will not be received with greater enthusiasm than Rieck's proposal. Gaucher has saved 17 cases by this method, and Dubousquet has treated 81 cases with a mortality of only five per cent. Gaucher's method, by the way, is nothing new, for a German physician proposed the same treatment in 1885. Your correspondent in that year assisted Prof. Henoch, of the Royal Charité, in the cauterization of deposits in a grave case in a girl thirteen years old. The girl recovered and, as Prof. Henoch thought, only as the result of this treatment. Nevertheless, the cauterization treatment has never been adopted by Prof. Henoch nor by any other German pediatrist. It is clear, that this treatment can only be of avail in the initial stage of the affection, before the specific germs have entered the circulation. Besides, the treatment is undoubtedly too heroic ever to become popular.

Adherence to false conceptions of honor and to medieval and barborous usages has again resulted in the death of a human being, this time a youthful medical student of the Berlin University. A mere difference of opinion, and the assertion that academical associations, the chief principles of which consist in antisemitic tendencies, are a disgrace to German Universities, led to a duel with pistols, three rounds at ten paces. Young Blum was shot through the left lung, and died immediately. It is a shame and disgrace that in an enlightened country such as Germany, and among its most intellectual associations, such barbarous and outrageous customs should still exist. Not a year passes that the "code" does not demand its victim or victims at some of the German Universities. I believe that the fault is entirely with the Government, and that severe punishment of the murderers will alone prevent the further perpetration of this atrocious crime. The great trouble in this matter, however, is the fact that the highest officials of the Government have all been ardent advocates of the code, and that they cannot well condemn in others what they have upheld themselves. Mere fencing, which is the universal custom among all German students, though from an American point of view scarcely commendable, is, nevertheless, regarded in Germany as absolutely necessary to the maintenance of a proper *esprit de corps* among the students. As the result of this view and practice every other student whom you meet at Berlin or any other German University has a more or less lacerated face, of which he feels very proud. He exhibits his facial scars with the same pride and self-consciousness as, for instance, an officer his medals and orders. In some future letter I will write more about the German students and their habits. J. S.

PERISCOPE.

Poisoning with Cyanide of Mercury.

At the meeting of the Berlin Medical Society, November 21, 1888 (*Deutsche med. Wochenschrift*, Nov. 29, 1888), Virchow demonstrated specimens from a case of poisoning with cyanide of mercury, which presented a series of anatomical changes analogous to those described by him as occurring in poisoning with corrosive sublimate. The patient from whom the specimens were taken was a young man who had poisoned himself, but who survived eight days, so that the changes produced by the poison were very completely shown. The parts of the digestive apparatus above the pylorus, with which the poison came in contact first, presented no noteworthy changes of any kind, and especially no traces of erosion. The more marked changes began in the lowest section of the ileum. In a characteristic manner the affected areas occur at intervals, always on the flexures of the colon, while between these areas are comparatively normal stretches of tissue. The kidneys throughout the cortex, but preferably the convoluted tubules, are filled with lime to a much greater extent than in any of the cases hitherto described. Virchow explains this result by saying that the mercury had acted upon the bones so that the lime salts were set free in the circulation; thence they were carried to the kidneys, which were inflamed by the effort at excretion.

Foreign Body in the Larynx.

At the meeting of the Medico-Chirurgical Society of Glasgow, Oct. 12, 1888 (*Glasgow Med. Journal*, Nov. 1883), Mr. George A. Clark read notes of a case of foreign body in the larynx, and exhibited the patient.

J. H., 9 years old, was admitted on August 16 into Ward 25 of the Royal Infirmary, suffering from what was described as fits, coming on, at irregular intervals, without any warning, and for which no cause could be assigned. Between the attacks, which lasted for variable lengths, the patient seemed in the best of health, was able to run and play about, and in every way enjoy himself; but when seized with a "fit" he became cyanotic, and after the seizure had passed off there was profuse perspiration with exhaustion. As the character of these attacks did not simulate those of epilepsy, and as no history could be obtained, the patient was kept under close observation. It was then noticed that these attacks, which were spasmodic, seemed to come on after the slightest attack of coughing or laughing, during which time the child had to sit up in bed; and although some attacks passed off in a few moments, others would last for some time, and when a constant irritating cough terminated in a severe fit of coughing the child would struggle for breath, and at times become so cyanotic as to be in danger of suffocation. It now became conclusive that the affection was in the larynx, and on inquiry from the parents it was learned that a bean was supposed to have gone down his throat. It seems that on the previous day he was playing with some other boys, during which time he had his mouth full of beans, and a bigger boy having run after him hurled him to the ground on his back and knelt on his chest, when, it was supposed, one of these beans went down his throat. On the morning after admission the throat was carefully examined with the aid of the laryngoscope, but nothing could be detected. During that day he had a few attacks, which, at times, became somewhat serious; but beyond causing great prostration, nothing serious followed. During the night he had attacks also, and on the following morning it was decided to perform tracheotomy; but after making preparations, owing to the absence of any positive proof of the presence of a foreign body, it was postponed, with the understanding that the operation should be done only if an attack should come on so severe as to threaten life. That same afternoon Mr. Clark happened to pass through the ward, when he saw the boy sitting up in bed playing dominoes with two others. A few seconds later he was followed by one of the boys, who said that the child was choking. On returning, the boy was found lying back in bed quite cyanotic, and his breathing short and hurried. Mr. Clark immediately held him up by the legs and smacked his back, but this decidedly made him worse. His breathing became slow and gasping, and he seemed half insensible, so tracheotomy was performed low down. On opening the trachea immediate relief was given, and as the operation was only done as a palliative measure, the tube was introduced. That night little if any spasm took place, and the patient passed a fairly comfortable night. On the following morning the tube was removed and the trachea examined, but nothing could be detected. The tube was again introduced, but the spasms still continued, and at times became so troublesome as to be only checked by the inhalation of a few drops of chloroform. During these attacks Mr. Clark noticed a distinct "click" as of something coming up from below and striking the lower end of the tube; and the patient himself said he could feel something rising and falling. The temperature which had been high had fallen since the operation, and as the spasms were also decreasing the tube was ordered to be removed. No bad effects followed this, and as the throat showed signs of laryngitis it was suggested that only this was the cause of the spasms. Potassium bromide was therefore given; but it was soon noticed that as the wound began to close the temperature began to rise and the spasms to increase in severity. By September 1 the wound had quite healed, and the patient had a very severe spasm during the night, which had to be allayed by the inhalation of chloroform. On the following night Mr. Clark was again called, being told that the child was threatened with convulsions. He again found him in an asphyxiated condition, and resolved to perform tracheotomy again, if possible to satisfy himself that there was nothing present. Accordingly the old wound was opened up and a free opening made in the trachea. The trachea was then opened up well with retractors, which caused a severe spasm of the glottis. Mr. Clark then watched closely, and after some time noticed something occasionally rise and immediately fall. This was dark in color, and at first sight seemed like a clot of blood, but after being successful in touching it, he

was satisfied that some solid body was present. He then took a tracheal hook and opened up the trachea with the retractors to cause a spasm, and, watching his opportunity, succeeded when the body rose in placing the hook beneath to prevent its return. He then managed to turn the hook round, and pinning it, withdrew it. The foreign body turned out to be a horse-bean, and its removal gave, of course, immediate relief. The wound was dressed, and healed rapidly. There was no return of spasms. The patient was dismissed September 9.

Inoculation with Leprosy.

The *Lancet*, Nov. 24, 1888, says that Archdeacon Wright lately called public attention in *The* (London) *Times* to the spread of leprosy, and the evidence of its contagiousness. He now furnishes a report from the Board of Health, Honolulu, giving information of the condition of a condemned criminal at Oahu Gaol who was inoculated with leprosy by Dr. Arning on November 5, 1885. Dr. Emerson, the President of the Board of Health, and Dr. Kimball examined this man on September 25, 1888, and reported that he presented marked signs of tubercular leprosy. Archdeacon Wright thinks that this "terrible experiment" goes far to prove the contagiousness of leprosy; and there is no doubt that such an experiment is proof of its inoculability. But we venture to think that the case for contagion is not rendered any stronger than it was already by the facts of the disease and of its nature gathered from various sources of late years; and it is questionable whether the transmission of such a disease by inoculation, even on a condemned criminal, is an experiment that ought rightly to have been made.

On the other hand, in a letter to the *British Med. Journal*, Dec. 15, 1888, H. P. Wright, Rector of Greatham, gives the following important particulars, which were contained in a letter to him from Dr. Arning, who asks a very reasonable question: "The experiment was performed after mature deliberation, and on the authority of the advisers of the Crown and the Privy Council of State; influential foreigners, laymen, and learned judges reporting in committee on the subject. It was done with the condemned criminal's written consent, and with all such due care and exactness as really to advance our knowledge of the obscure disease. Will it not stand as having been done in the interests, not against the laws, of humanity?"

Purulent Pericarditis; Aspiration and Drainage.

At the meeting of the Clinical Society of London, Nov. 23, 1888, Dr. Dickinson related the case of a boy, 10 years old, who was brought to St. George's Hospital, having had symptoms which Dr. Harris and Mr. Noad, both of Norwood, interpreted as pyæmic. A large gluteal abscess was followed by signs of pleural effusion and œdema of the face and chest. On admission, on June 15, 1887, there was evidence of effusion in the left pleura and in the pericardium. The position of the heart was almost indiscoverable amid the dulness, which involved the left pleural and præcordial regions. There was much dyspnœa, blueness, and irregularity of pulse. There was œdema more or less general, but especially marked about the thorax. The liver was enlarged or depressed so as to reach the umbilicus. On the 18th the pleura was aspirated, and thirty-seven ounces of serum were drawn off, which operation was repeated on the 23d, with the removal of thirty-two ounces. The dyspnœa, blueness, and œdema were but slightly and temporarily relieved by each operation, which had to be repeated on the 25th and 28th, so great was the distress and so rapid the reaccumulation. On the 30th the futility of dealing with the pleura having become apparent, the pericardium was aspirated by Mr. Rouse, and one ounce of creamy pus withdrawn; the aspiration was repeated with more success on July 8, twelve ounces of similar fluid being withdrawn, and on the 15th, with the withdrawal of nineteen ounces. The place selected for puncture was on the right side close to the edge of the sternum, in the fifth interspace. The heart before each of these operations had been drawn to the left by a preceding evacuation of the pleura. The lower part of the pericardium where the swing of the heart was greatest, and the right extremity of the cavity, from which the heart was furthest removed, was obviously the part which could be penetrated with the greatest safety. By July 22 the pericardium was again as full as ever, and the general symptoms as distressing. It was clearly necessary to replace aspiration by a tapping opening. Mr. Rouse accordingly made an incision where the punctures had been, and put in a tube. The aspiration was followed by some faintness, but subsequently by great relief. Not to follow the case in further detail, recovery, after some temporary drawbacks and three subsequent aspirations of the pleura,

became complete. By the middle of September there was no remnant of the pericardial puncture except a small cicatrix, which moved with each beat of the heart. In the course of less than two months the chest had been punctured sixteen times, the pleura twelve times, with the removal of serous fluid; the pericardium four times—thrice with the aspirator, once with a knife—so as to leave an opening and a constant discharge of pus. A remarkable fact in the history of the case—one, however, not unprecedented in similar circumstances—was the nearly total absence of præcordial friction, which was recognized only on one occasion.—*British Med. Journal*, Dec. 1, 1888.

Meningocele; Ligation and Removal of Sac.

Dr. W. O. Roberts, Professor of the Principles and Practice of Surgery, University of Louisville, in communicating this case to the *American Practitioner and News*, Dec. 1, 1888, says that on March 19, 1888, he saw, with Dr. Milner, of Uniontown, a child five weeks old, who had a pedunculated tumor, about the size and very much the shape of a goose egg, situated just beneath the occipital protuberance. The history of the case was as follows: The growth was first noticed immediately after the birth of the baby. It was then about one-half its present size. When the child slept the tumor was much smaller; and would become suddenly greatly swollen and tense when it cried. The tumor had always been exceedingly sensitive to the touch, and the slightest pressure upon it caused the child to cry violently. In consequence, it had never been able to lie on its back. Dr. Milner was called in a few days before Dr. Roberts saw it, and tapped the growth and drew off a quantity of serous fluid slightly tinged with blood. This diminished the size, of course, but did not lessen the sensitiveness of the growth. He then advised that the child be brought to Louisville, where Dr. Roberts saw it with him. At the time of the latter's visit the child was asleep in its mother's lap, lying on its abdomen. Hanging from the occiput was a flabby tumor. Just as he touched the growth the child awoke, crying violently. There was an immediate and great distension of the tumor. The pedicle or attached portions measured five and the body of the tumor eight inches in circumference. The skin over the tumor was well covered with hair. Fluctuation was marked. There was no pulsation. The growth was unmistakably a meningocele.

As the growth was increasing rapidly in size, and as the sensitiveness had not diminished a particle after Dr. Milner had partly drawn off the fluid, its removal was advised. The parents, having been fully advised of the nature of the affection and the danger of the operation, decided to have it performed. On the following day Dr. Roberts removed the tumor. An elliptical incision was made through the skin and fascia covering the neck of the sac. This was first carefully dissected, then transfixed and ligated close up to the edge of the opening in the skull with a double stout silk ligature, and the tumor cut through in front of the ligature. As the ligature was tightened the child had a slight convulsion. When the tumor was opened nearly three ounces of a slightly bloody serous fluid escaped. The cyst was sacculated. There were three sacculi connected with the main cavity of the cyst. No brain substance was found in it. The opening in the skull was just below the occipital protuberance, and was about an inch in its vertical and half an inch in its transverse diameter. The ends of the ligature around the neck of the sac were cut short, and the integuments then brought together, provision being made for drainage. The operation was done under strict antiseptic precautions. Recovery took place without an untoward symptom. At the end of ten days the wound had healed, and the child was taken to its home. Three months after the operation the child was reported to be in perfect health, with no recurrence of the tumor.

Case of Polyuria with Localizing Symptoms.

At the meeting of the Pathological Section of the Medico-Chirurgical Society of Glasgow, Oct. 19, 1888 (*Glasgow Med. Journal*, Nov. 1888), Dr. Alexander Robertson read the notes of a case of polyuria.

A patient was shown suffering from diabetes insipidus of about eight months' standing. He was a soldier for some years, and is now about 30 years of age. Careful examination failed to elicit any indications of syphilis, and none were admitted. His illness dates from about six months before admission into the Infirmary, which was on the 2d August last. He had lost about 28 lbs. in weight in the earlier months of his malady. No probable cause could be

assigned. The amount of urine ranged from 150 to 190 ounces in 24 hours, though once it had reached 290 ounces. The specific gravity was generally from 1003 to 1006. It was always free from albumin and sugar. Dr. Ritchie had found that the quantity of urea excreted in the 24 hours was 479 grains. There were no general symptoms of renal disease. Though scarcely any appreciable difference existed between the two sides of his face when at rest, movements which called into action the lower facial muscles—*e.g.*, showing his teeth, the articulation of certain words, etc.—showed that the right side was distinctly weak. On many occasions, especially during the last three or four weeks, he had sudden attacks of difficulty in speaking, lasting from 20 minutes to 24 hours. They were preceded in most cases by a feeling of sleepiness. The defect was in articulation—a marked stammering, with special difficulty in the beginning of a sentence; there was no loss of language. Dr. Fergus reported that there was a moderate degree of neuro-retinitis, and that the movements of the right pupil (the sight of the left eye being damaged by an old injury) were restricted, not responding much to light, or accommodation, or cutaneous irritation. The pupil itself was moderately contracted. The pulse ranged between 50 and 60. Without inquiry he stated that he had often a feeling of chilliness, but that sometimes he had only become aware of this fact by the remarks of his friends on his pale, cold aspect. Besides this, several times he had felt the right ear very hot. Dr. Robertson had seen it in this condition, and said that it was scarlet from the injection of the blood-vessels, and that the redness extended to the cheek. The contrast with the other ear was very marked, as it was blanched and chilly. There was no undue secretion from the eye or nose. General sensation and motion had never been affected. Consciousness had not been involved, and his general intelligence was good.

In reviewing the facts of the case, Dr. Robertson said: As you are aware, Claude Bernard induced a glycosuria by puncturing the floor of the fourth ventricle, and by puncturing, a little higher up, a polyuria. Still, there are wanting cases in the human subject corroborating the idea that the lesion is in that part of the brain; but this case clearly supports the indications derived from Claude Bernard's experiments. The speech being affected in the manner described pointed to temporary disorder in the nucleus of the ninth nerve. But there is an organic and more permanent defect of the facial nerve present, the nucleus of which is a little higher up, but not far from the same situation. Also we have temporary irritation and palsy of different parts of the vaso-motor nerves, the centre of which is situated there also. There is probably an important controlling centre of the vaso-motor system in the cortex of the brain, but we also know that there is a centre of great importance in the medulla oblongata. Further, the slowness of the pulse may indicate an inhibitory influence on the pneumogastric nucleus, but the reduction in the number of pulsations did not warrant much stress to be laid on this point. We have, then, these indications of disease independent of the polyuria altogether. The state of the pupil might also suggest some degree of paralysis of the sympathetic. The pupil is generally somewhat contracted, which may no doubt be due to stimulation of the nucleus of the third nerve; but in view of the other indications of vaso-motor paralysis, we may conclude that not improbably this condition of myosis is due to the same cause. With regard to the polyuria, what is it to be ascribed to? Is it due to trophic nerves whose function is impaired, though their existence is still called in question; or is it rather due to a paralysis of the vaso-motor nerves of the kidney? Dr. Robertson held that the latter view was much the more probable, considering the clear indications of general disorder of the sympathetic which were obvious in the case. He thought there was distinct change of nerve-structure present, though scarcely amounting to a definite tumor.

Medicinal treatment, the details of which were mentioned, had not been of much use. It was, however, intended to try galvanism passed through the medulla oblongata.

—Dr. R. Brudenell Carter, of London, according to the *American Lancet*, Jan., 1888, says that when he sees a pamphlet or book purporting to contain an addition to our knowledge, he tries first of all to ask himself: "What do I know of the author? What is his character, in the estimation of those who know him well, for sagacity, dexterity, and truthfulness? What is the extent of his experience? What are his claims to be received as a guide and instructor in the matters with which he attempts to deal?" If these questions are fairly answered, the pamphlet will sometimes be relegated to the waste basket.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.00**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

JUDICIOUS MANAGEMENT OF A CASE OF SUPPOSED HYDROPHOBIA.

Near the end of last December Dr. Healy, of Philadelphia, was called to attend a very ill young man who had a history of a dog-bite and certain symptoms of hydrophobia. In conference with Dr. Wirgman, he decided to invite to consultation a medical man who is well known as a specialist in nervous diseases, and another who had made a special study of hydrophobia.

When the consultation was held a very careful and thorough examination of the patient was made, and it was found that he presented clear evidence of disease of the brain. He had some paralysis of one arm and paresis of the muscles of the mouth and throat. He had a most typical difficulty in swallowing liquids, unaccompanied by any real pain. This was exactly like the symptom to which the name "hydrophobia" is most fitly applied. It was wholly due to want of power or of co-ordination in the muscles of the mouth and fauces, and not to any notion of the patient that he was suffering with rabies humana. This fact was ascertained to the entire satisfaction of all of the consultants.

The case was regarded as one of disease at the base of the brain—perhaps in the pons Varolii—and treated accordingly.

The condition of the patient, at the time of the consultation, was so grave that little hope was entertained that he could recover; and, as was anticipated, he died in a few days. The cause of death was not hydrophobia, however, and the case will not go to increase the fear of this disorder. We call attention to it chiefly to applaud the judgment of the physicians immediately in charge, who secured what we regard as an ideal consultation. They themselves were thoroughly competent to judge of the purely general medical aspects of the case, and they secured the counsel of a man familiar with the difficult problems of disease of the brain and spinal cord, and of one who had made hydrophobia a subject of special study for years at the bedside and in medical literature.

We believe that it would be of incalculable value to our science if every case of suspected hydrophobia could be thus studied, carefully and without bias, by men skilful in general diagnosis, who would not fail to recognize any underlying constitutional or local disease which might cause dysphagia, and men trained to detect the evidences of disease of the brain and spinal cord. By such a combination the danger of an error of diagnosis would be reduced to a minimum, and we have no doubt that in many cases the fatal result which usually follows a diagnosis of hydrophobia would be averted.

PROTECTION FOR AMERICAN PHYSICIANS.

A recent editorial in the *Medical Record*, making a plea for the protection of American physicians against the competition of German physicians, who come to this country to practise, has been somewhat misunderstood by the *Press* of Philadelphia, which takes the *Medical Record* to task, and asserts that the community needs protection against incompetent physicians—native as well as foreign. The *Press* editorial will be found in another column.

In this the *Press* is undoubtedly right, and no one, we are sure, will endorse its sentiments more heartily than the *Medical Record*. It is unfortunate that the title and contents of the editorial in the latter journal are misleading, and that it seems to lay more stress upon the nationality of the competing physicians and the cheapness of their charges than upon the imperfection of their medical training. As a matter of fact, American physicians need no legal protection against any class of competitors, except on the ground of unfitness for their work; and our lay contemporaries must not mistake a local wail for a general complaint. In New York the social and professional conditions are peculiar, and largely influenced by its enormous foreign population. It is, in important respects, unlike any other American city, and probably less American than any other. No doubt some of its physicians are inconvenienced by the natural consequences of its peculiar make-up; but this is a purely local matter, and of no interest outside of New York.

All over the United States the members of the medical profession are content to protect themselves, and to secure respect and patronage by deserving it. They are the strongest advocates of a high standard of medical education, and welcome every evidence that the community is awaking to the necessity for exacting this from those who intend to practice medicine. They will not endorse any effort to secure discrimination in their favor for other reasons than those of merit, and the best of them would be glad to have the State take intelligent charge of the regulation of medical practice and abolish all the privileges of the mere title of M.D., requiring a license to practice, which should be issued only to those who pass a satisfactory examination before a Board of Examiners appointed by the State.

This is the kind of protection which every intelligent citizen would approve, and which we hope some day to see established in this country.

ABORTION IN CHICAGO.

The *Chicago Times* has recently been investigating the subject of criminal abortion in Chicago, by means of a decoy, who visited a large number of midwives and physicians, pretending she was pregnant and asking them to help her out of her dilemma. The results of this investigation were published in December, and they show that a woman who is ready to undergo the risks of an abortion in Chicago need not search hard to find a medical man to share them with her for a consideration.

The issue of the paper for Dec. 17 contains a list of midwives and physicians in Chicago who would bring on an abortion—one of the latter being the official surgeon of the Police Department, and a supplementary list of men who declined to commit this crime themselves, but recommended others who would do it.

The same issue contains a letter from Dr. Doering, President of the Chicago Medico-Legal Society, expressing approval of this investigation and promising the support of the Society to its work. This fact may be taken as an index of the attitude of every decent medical man in the United States; for there are no more uncompromising enemies of the crime of abortion for convenience than physicians; and the fact that some men or women, whom the lax laws

of most of the States permit to practice medicine, are willing to use the knowledge they have in an infamous way simply illustrates the adage that black sheep are to be found in every flock.

We cannot approve of the sensational way in which the *Chicago Times* has been exploiting its discoveries in regard to the crime of abortion in Chicago, and fear that it may do much harm by advertising the methods of abortionists; but we trust that this serious disadvantage may be offset by the fact that it is also calling attention in a most striking way to the heinous character of this offense against public morals.

ELECTION OF PROFESSORS AT THE UNIVERSITY OF PENNSYLVANIA.

At the last regular meeting of the Trustees of the University of Pennsylvania, Dr. John Ashhurst, Jr., now Professor of Clinical Surgery, was elected to the chair of general Surgery vacated by the resignation of Dr. Agnew, and Dr. James Tyson, now professor of Morbid Anatomy and General Pathology, to the chair of Clinical Medicine, made vacant by the resignation of Dr. Osler. The title of Emeritus Professor of Surgery and Clinical Surgery was conferred on Dr. Agnew. This action of the Trustees will make two more vacancies: one in the chair of clinical surgery, and one in the chair of morbid anatomy and general pathology. It is commonly believed that the former of these positions will be secured by Dr. J. William White, of Philadelphia, and the latter by Dr. John Guitéras, of Charleston. Dr. White is now Clinical Professor of Genito-Urinary Surgery and Demonstrator of Surgery in the University, and Dr. Guitéras is a graduate of the University, who was formerly one of the Visiting Physicians to the Philadelphia Hospital, and enjoyed an enviable reputation as a diagnostician and clinical lecturer. He is at present Professor of Pathology in the South Carolina Medical College, and a surgeon in the U. S. Marine Hospital Service.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

DIE GESCHICHTE DER TUBERCULOSE. Von Dr. med. AUGUST PREDÖHL, assistenzarzt am allgemeinen Krankenhause zu Hamburg. 8vo, pp. 502. Hamburg und Leipzig: verlag von Leopold Voss, 1888.

This is an important contribution to the history of the development of our ideas concerning tuberculosis, showing how they emerged from dimness and gradually assumed a definite form. Even the earliest writers on the subject recognized the presence of nodular bodies in diseases of the lungs, which they called tubercles, but which would hardly come up to the more modern acceptation of that term. All the so-called lung tubercles of that time were contained within the vesicular structures. But here, as in everything else, our knowledge advanced from the simple to the complex, and disease within the air cells was of easier recognition than that without. Stark, in 1785, was the first to realize that the lungs became studded with small nodules, the composition of which he believed to have been coagulated lymph. Both Laennec and Louis, following Bayles, admitted but one kind of phthisis—the tubercular. Rokitansky, in 1845, was the first to distinguish between true and false tubercle; and he termed the first: interstitial tuberculosis, and the second: pneumonia. Engel and Hamernyk agreed with Rokitansky; but Addison, who held that tubercle is due to a proliferation and accumulation of epithelial cells, was probably the first to comprehend the true nature of the intra-vesicular nodule. It was not, however, until 1854 that the illuminating mind of Virchow defined the nature and proper relation of these structures, as follows (a) tubercle, or miliary tuberculosis,—a hyperplasia (neubildung) of lymphatic tissue; (b) pseudo tubercle—an inflammatory product.

With Villemin began a period of experimental investigation, which, ending with Koch, tends to overturn the exact ideas of the earlier workers in this direction. The criterion of tubercle now is the bacillus, and the nature of a product is judged in relation to the presence or absence of this micro-organism. Investigation shows that the bacillus is found in the false as well as in the true tubercle. There is no reason to find fault with this drift of things, if the bacillus theory tends to place our knowledge of tubercular diseases on a more scientific basis than it has heretofore occupied. It is evident, however, that the bacillus is not satisfied with anything short of the whole earth, for just so soon as it became a recognized element in the diagnosis of tubercle, it also began to play the rôle of an etological factor. In the first, it is a success; in the second, it is a failure. Clinical, and not experimental, medicine must render an ultimate decision as to the etiological relation of the bacillus tuberculosis, and this otherwise very valuable work is slightly defective in not giving a more complete history of the clinical statistics which have already been garnered, and which substantially show the worthlessness of the bacillus as a practical cause of tuberculosis. Reference is made especially here to the Brompton Hospital statistics, and to the *Statistical study of the Etiology of Phthisis Pulmonalis*, contributed by Dr. Schnyder to the *Correspondenz-Blatt für Schweizer*

Aertzte, 1886, Nos. 10, 11 and 12; both of which are left unnoticed in the book before us.

The book as a whole is of uncommon interest, and we sincerely trust that it will obtain a large number of readers on this side of the Atlantic.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

180. Mineral and Thermal Springs of California. By W. F. McNutt, M.D., San Francisco, Cal. From the *Transactions of the Ninth International Med. Congress*, vol. v, 9 pages.

181. Double Ovariotomy During Pregnancy; Subsequent Delivery at Term. By William Warren Potter, M.D., Buffalo, N. Y. From the *American Journal of Obstetrics*, October, 1888. 4 pages.

182. Sulfanol, the New Hypnotic. By B. Sachs, M.D., New York. From the *Medical Record*, October 6, 1888. 8 pages.

183. Valedictory Address at the Commencement of the Departments of Medicine and Dentistry of the University of Pennsylvania, May 1, 1888. By John Ashhurst, Jr., M.D., Philadelphia. 14 pages.

184. A Peculiar Case of Herpes Zoster Ophthalmicus, Serous Iritis, or "Ophthalmo-Neuritis." By George M. Gould, M.D., Philadelphia. From the *Polyclinic*, October, 1888. 6 pages.

185. Transactions of the American Association of Obstetricians and Gynecologists. First Annual Meeting. Abstract. From the *Buffalo Med. and Surg. Journal.*

186. Graduated Tenotomy in the Treatment of Insufficiencies of the Ocular Muscles. By Charles Hermon Thomas, M.D., Philadelphia. From the *Transactions of the Philadelphia County Med. Society*, 1888. 12 pages.

187. Report of Proceedings of the Illinois State Board of Health. October, 1888. The Yellow Fever Epidemic of 1888, Etc. 25 pages.

188. Peri-Cæcal Inflammation. Pathology. By John H. Musser, M.D. Diagnosis. By William Pepper, M.D. Treatment. By Thos. G. Morton, M.D. From the *Transactions of the Philadelphia County Med. Society*, 1887. 19 pages.

180. This pamphlet, as its title indicates, gives an account of the various springs of California which are of value in the treatment of diseased conditions. It contains useful information as to the location of these resorts, and tables of analyses of the constituents of many of the waters.

181. Dr. Potter reports the first case of which he has knowledge in which a double ovariotomy during pregnancy was followed by delivery at term. His patient was in the fourth month of pregnancy. The history of the case is exceedingly interesting.

182. The spelling of the title of this pamphlet is probably chargeable to the Editor of the *Medical Record*, and not to the author, as he could hardly have made such a mistake. The substance of the paper is a report of Dr. Sachs's experience with sulphonal in eleven cases. He finds—as most men who use it have found—that sulphonal is a good hypnotic in cases of functional insomnia; and that it has very little narcotic influence.

183. Dr. Ashhurst's address contains kindly and valuable advice to those for whom it was prepared, and is of such a character that it is not surprising to find the name of a bishop heading the list of those who asked him for a copy for publication.

184. Dr. Gould gives the history of a case of ophthalmo-neuritis with some peculiar symptoms. His report will interest ophthalmologists on account of the curious features of the case, and its developments under treatment.

185. The contents of this pamphlet are indicated fully by its title. The cover states that it is from the *Buffalo Med. and Surg. Journal;* the first page credits it to the *Amer. Journal of Obstetrics.* The contents are interesting and instructive; and, as might be expected, there is rather a preponderance of gynecology over obstetrics in it.

186. As Dr. Thomas's paper was published in full, with the accompanying plate, in the Reporter, April 14, 1888, its contents are probably familiar to most of our readers. It advocates and illustrates the advantages of the method of treating insufficiency of the muscles of the eyeball proposed by Dr. Stevens, of New York, to which we have more than once called attention in these pages.

187. This report, prepared by Dr. Rauch, contains some very instructive reading in regard to the history of the recent yellow fever epidemic and the absurd and damaging methods adopted to limit its spread. We can heartily commend it to the attention of our readers, in the hope that it may correct some false notions in regard to yellow fever, which experience teaches are entertained by medical men as well as by the laity.

188. These papers, with the discussion which followed their reading, were published in the Reporter, Jan. 7, 1888, and they are so valuable that we can recommend those who have become subscribers since that date to endeavor to get a copy of this pamphlet and make themselves acquainted with its contents.

Literary Notes.

—Commencing with the January, 1889, number, the name of the *Sacramento Medical Times* will be changed to the *Occidental Medical Times.* The journal will be enlarged to 56 pages and the subscription will be reduced to $2.00.

—The *Internationales Centralblatt für die Physiologie und Pathologie des Urogenitalsystems* is the title of a new journal about to appear in Germany. Among the members of the editorial staff are Profs. Preyer and Zülzer of Berlin.

—The *Alabama Medical and Surgical Age* began its course in December, 1888, under the editorial management of Dr. John C. Le Grand, at Anniston, Ala. The first number is an octavo of 26 pages, containing a good deal of interesting matter, and an appeal for support in the State of Alabama which deserves a hearty response. The fact that it is the only medical journal now published in a State which has a large and able body of physicians makes its appeal especially worthy of consideration. It is to be issued monthly; subscription price $2.00, payable in advance.

CORRESPONDENCE.

"Grass Bur" in Left Bronchus.

TO THE EDITOR.

Sir: I notice in the REPORTER of Dec. 8, an account of a case of "Sand-Bur in the Larynx," which recalls to my mind a somewhat similar case occurring in my practice about five years ago, while practising in Texas, and perhaps it is worthy of recording.

I was called to see the patient, a boy four or five years of age, and found him with a high temperature, severe pain in the left side, rapid breathing, with cough and muco-purulent expectoration. On physical examination I found entire absence of respiratory murmur on the left side, and all the symptoms of pneumonia; and such was my diagnosis. I visited him daily and found no improvement in the lung. On about the sixth day, after examining him—and while I was giving some direction in regard to his medicine, he was seized with a violent fit of coughing, and then began to cry, telling his mother that something was sticking him. The mother, using her handkerchief to clear the mucus from the boy's mouth, brought out something and passed it to me. This on inspection proved to be a "grass-bur"—the name applied to a bur, or ball that is covered with very sharp spines or "stickers," the whole thing being perhaps one-fourth of an inch in diameter, and the product of a species of grass indigenous to Texas. The only information I could get to explain how this foreign body found its way into the lung, was from the mother, who recollected that some weeks before the child, while running and playing in the yard, fell down and began to cry as though severely hurt, but soon seemed all right, and nothing more was thought of the occurrence until the bur was expelled from the lung. The patient began to improve from that time and made a complete recovery.

To those who are familiar with the "grass bur," it will seem strange that such a formidable body could enter the bronchi without causing symptoms of a more violent character.

Yours truly,

T. A. CRAVENS, M.D.

Los Angeles, Cal.,
Dec. 20, 1888.

—The town of Nanticoke, Penna., is alarmed over some cases of small-pox which exist within its limits.

NOTES AND COMMENTS.

Effect of Glycerine on the Quantity of Secretion poured into the Vagina.

At the meeting of the Obstetrical Society of London, Dec. 5, 1888, Dr. Herman read a paper which related observations made to see whether the commonly, but not universally, accepted belief, that the local use of glycerine causes a flow of fluid from the vagina, was correct or not. The observations were made with cotton-wool plugs soaked in glycerine, and with pessaries made of gelatine and glycerine. The amount of glycerine inserted into the vagina was weighed; the discharge from the vagina was weighed, and the amount of vaginal discharge from the same patient when glycerine was not used was also ascertained by weight. The result of the observations was in favor of the following conclusions: 1. That when the secretions poured into the vagina were not abundant, the local use of glycerine increased them. 2. That when the secretions poured into the vagina were already abundant the local use of glycerine did not increase them.

Dr. Champneys asked if Dr. Herman had estimated the loss on the diapers from evaporation. The conditions were favorable for evaporation, and would confirm the conclusions arrived at in the paper.

Dr. Herman, in reply, stated that he thought the loss of weight by the napkins or pads due to evaporation was but slight; on the other hand, the perspiration from the skin with which the napkin was in contact, might cause a slight increase in weight. Dr. Herman had used the words "secretions poured into the vagina," which did not imply any opinion as to their source. Whether the secretion was of uterine or vaginal origin, whether it was produced by glandular activity or simple osmosis, he could not tell. He would be obliged if Dr. Griffith could suggest any method, harmless to the patient, by which the excretions of the uterus could be separated from those of the vagina. Dr. Herman believed that the vagina did secrete mucus. In cases of atresia of the vagina at more than one place, collections of mucous fluid were found between the occlusions. In cases of atresia of the os externum, the vagina was as moist as in most other patients. That under pathological conditions the vagina might pour out fluid in abundance needed no demonstration.—*British Med. Journal*, Dec. 15, 1888.

Electrolysis for Alterations in the Prostate caused by Gonorrhœa.

At the recent meeting of the Southern Surgical and Gynecological Association, held at Birmingham, Ala., Dr. J. D. S. Davis read a paper in which, after establishing the true physiological reason, as he thinks, for the use of electrolysis in hypertrophy of the prostate, based on well-known physiological facts, he gave explicit directions as to the method of its use. He emphasized the great importance of a good galvanometer and rheostat, next to a reliable battery. He recommended the nickel-plated insulated *bougie à boule*. The cutaneous electrode should be large, and applied to the abdomen. In order to obtain the maximum therapeutic effect, the cathode must be introduced into the prostatic urethra, and a very weak current passed through it (to avoid shock, the rheostat should always be used), increasing gradually until the galvanometer registers the required number of milliampères.

The method of *Electrolysis* is simple, and can be executed by the physician without aid; it is painless, requiring no anæsthetic; very little inconvenience is felt after the operation, and anodynes are never required; it is absolutely harmless; it is antiseptic on account of the energy of the low chemical current employed: and electrolysis, which is called galvano-chemical absorption by Newman, is always followed by a process of retrogression and disintegration.

A focus of derivation is created in the diseased gland, which is analogous to what is caused by a profound shock of the muscular system from over-exertion or over-stimulation, and which continues after the cessation of the current; transforming the temporary shock, which the passage of the current has transmitted, to the muscular element of the prostate; and it finally inaugurates a process of retrogression, disintegration, and absorption.

The muscular tissues are relaxed by the powerful stimulating effect of the current; the vessels are relaxed; and the blood-flow is increased by diminishing the capillary resistance; and absorption readily takes place.

Of galvano-chemical absorption, Dr. Davis says: "I understand that it is a chemical decomposition, which borrows its immediate effects from the suppurated albuminous bodies through the constituents of tissue; and not as defined by Newman as 'The process or act of being made passive by the disappearance in some other substance, through molecular or other invisible means, as absorption of light, heat and electricity,' which, though it is Webster's definition of absorption, is only a vague descriptive picture of the disappearance of animal structures."

The author concludes that a favorably-adjusted galvano-chemical current of low intensity will produce a decomposition of the tissues of the body, without resulting in or producing galvano-chemical cauterization of the superficial layers.

Electrolysis, while applicable to all strictures of the urethra, is of permanent benefit in the morbid alteration of the prostate produced by gonorrhœa of the urethra. It has an anæsthetizing influence upon the terminal nerves at the point of application; and by causing muscular exhaustion, it produces early relaxation of spasm, and thus aids in overcoming spasmodic urethral strictures, following the over-stimulation by natural reproductive processes; it excites absorption, and relieves the patient.

Intestinal Obstruction With Linseed.

Dr. Polaillon lately brought to the notice of the Academy of Medicine of Paris a curious effect of linseed, which is frequently prescribed in grain for obstinate constipation. He had under his care a young woman in good health, but habitually constipated, who took daily for three months a tablespoonful of linseed in grain. At the end of this time she showed symptoms of intestinal occlusion, and after complete constipation, lasting for a week, it was found necessary to make an artificial anus, through which an enormous quantity of linseed escaped. Notwithstanding this relief, the patient continued to sink, and died seven days after in a markedly typhoid state. Dr. Polaillon recalled a similar circumstance reported by Professor Verneuil, of obstruction produced by fig-seeds. He thinks that in his own case surgical intervention was too late, and that the woman had succumbed to stercoræmia. Dr. Berger also recalled what takes place in animals which ingest these same products without bruising them, and of which they easily disembarrass themselves. He had seen guinea-pigs fed with Indian corn in grain; their intestines filled like a sack of wheat, and they continued ingesting until the bowel was ruptured. It is probable that these differences between man and animals depend on the nature of the secretions.—*Lancet*, Dec. 15, 1888.

Protection for American Physicians.

Recently actors of the second and third grade have expressed a desire to be protected from the cheaper and perhaps better English article by a non-importation act; for "professional actors" are excluded from the operations of the present law. This actors' movement has struck the average public as absurd, but it is capped by the New York *Medical Record*, which in its issue of December 29 devotes its leading editorial to an earnest plea for protection for American physicians.

It complains that numbers of physicians, so-called, come over from Germany on every steamer. They possess a university diploma of M. D., which entitles them to practice as soon as they get here, though they could not practice in Germany because they have never passed, and are not able to pass, the state examination. Here, however, they have at once the legal status of a physician. They settle down in the German districts, put out a sign and pay visits for twenty-five or fifty cents. England, France and Italy make similar contributions annually to the number of practicing physicians of the United States. On this account, the *Record* says, "there is a growing feeling among physicians in New York City that if the principle of Protection be applied to some class of workers it might with equal justice be applied to the doctor."

It is not disputed that the ranks of physicians in this country are overcrowded. If, however, doctors need to be protected from incompetent Germans they need quite as much to be protected from incompetent Americans, who are turned out of the regular medical colleges by the wholesale and are authorized by their diploma to practice medicine with often an entirely inadequate preparation for their work. One diploma mill, we have in mind, graduates its young men after two terms or a total attendance of six months. Competent doctors may or may not think they require protection from this class of practitioners, but it is certain that the public do. It matters not whether the physician comes from Germany or from Kentucky, the fact that he holds a diploma from some alleged medical college ought not of itself without further proof of fitness to entitle him to practice his probable ignorance upon a suffering and defenseless humanity.

Germany is perfectly right in permitting no one to practice medicine there without passing the state examination. A like provision here would protect the doctors by keeping out thousands of competitors; but its chief recommendation is that it would protect the public in great measure from the quacks and incompetents who, armed with a diploma from some obscure college, now practice unchallenged on whomsoever they can persuade to entrust their health to their keeping.—*Philadelphia Press*, Jan. 3, 1889.

Case of Probable Poisoning with Creolin.

So much has been written lately in praise of creolin as a harmless antiseptic that the following case of probable poisoning with it, which occurred in the wards of Prof. Rosenbach, of Breslau, and is communicated to the *Therapeutische Monatshefte*, merits attention. In a primipara, 27 years old, after evisceration of a dead fœtus the uterus and vagina were washed out with a two per cent. creolin solution, in which procedure about one gallon of the solution was used. As the temperature rose on the next day to 102.4° the uterus was again washed out with one quart of a one per cent. creolin solution. On the following day the temperature was 100.5°, and for this reason and because of a somewhat fetid discharge, the uterus was washed out with about one quart of a one per cent. creolin solution, making the third washing out since the delivery of the woman, without any change in the good health of the patient occurring. In the evening about half-past six the uterus was washed out a fourth time. About nine o'clock the patient became suddenly pale and cold, and vomited violently. The temperature was 99°. The vomiting did not cease, sweating occurred, and at eleven o'clock the patient died in collapse and unconscious, after the temperature had fallen to 96.3°. The brownish-green vomitus smelt of creolin with extraordinary intensity. The distillate treated with bromine water gave a rich precipitate which had the characteristics of tribromphenol. The urine also smelt strongly of creolin.

The result in this case can not be attributed to heart failure, because the patient was pretty well just before death; nor to puerperal sepsis, for the result of the autopsy is opposed to this. Poisoning with creolin is indicated by the similarity of the symptoms to those of carbolic acid poisoning, by the unexpected death in collapse, the negative result of the autopsy, and by the character of the urine and vomitus.—*Wiener med. Presse*, Nov. 11, 1888.

A Threatened Revolt of Medical Students.

The trouble in the Medical Department of the University of the City of New York, to which reference was made in the REPORTER, Dec. 29, is not yet at an end. The students, it may be remembered, objected to the selection of a son of ex-President Woolsey, of Yale College, to be Professor of Anatomy, when they desired a favorite instructor, Dr. Weisse, to receive the appointment. In an address to the students, Jan. 2, Vice Chancellor MacCracken said that Dr. Woolsey had been definitely decided upon as the new Professor, and that Dr. Weisse's resignation had been accepted. Dr. Woolsey gave his first lecture Jan. 3, and the threatened revolt did not come off at that time. A few of the students left the room, but almost all remained, listened to their new lecturer with respect, and applauded him when his lecture was completed.

On Jan. 14, however, 86 dental students presented a paper to the Faculty formally notifying them of their withdrawal from the University. This secession includes all of the dental students in attendance. It is also said that the withdrawal of A. J. Walsh has left the College without anyone who knows the secret way of preserving bodies. The Faculty is therefore obliged to secure fresh bodies for dissection.

Treatment of Acute Coryza.

Dr. F. H. Potter, Lecturer on Laryngology in the Medical Department of Niagara University, makes some timely remarks on the treatment of acute coryza, in the *Buffalo Med. and Surg. Journal*, January, 1889. He considers pernicious the prevalent custom of sleeping with the windows open when the external temperature is below a certain point. At this time the temperature may suddenly fall, or through some restlessness on the part of the sleeper he may expose a part of his body to rapid cooling, and so contract a coryza. A cold bath should be taken in the morning in a warm room. If a bath-room is convenient, the water should be drawn and allowed to stand over night. The bath should be taken rapidly, so that the whole body will glow afterward.

No part of the body should be underclothed or over-clothed. It is important to keep the feet warmly covered, and to remove outside wraps upon going indoors where the atmosphere is warm. The neck-scarf should be worn according to the temperature of the day, when its use has become necessary to the wearer. Chronic affections of the nose and throat should be treated, for in patients so afflicted acute attacks of coryza may be only symptomatic of the chronic disorder.

If the cold comes on toward evening, the patient should take a hot bath, then 1-100 to 1-60 of a grain of atropine, and go to bed and be well wrapped up. If the atropine should disagree, a full dose of quinine, about ten grains, may be substituted. During the next day the nose and throat should be thoroughly washed with a warm alkaline spray. But a better plan is to employ the post-nasal syringe for irrigation; contract the turgescence of the nasal tissues with cocaine; and, finally, cover the entire surface with a coating of an unirritating oil. For this purpose he has found *oleum petrolinum* (fluid cosmoline) the best. The applications should be made three times a day. If the cold is first noticed in the morning, the process should be reversed—the local treatment given during the day and the general treatment at night.

By this method of treatment he says that colds which generally last from ten days to two weeks can be limited to about two days. When it fails some chronic intra-nasal disease will usually be found, or else some constitutional disorder which makes the attack of extraordinary obstinacy.

Idiosyncrasy as to Antipyrin.

Dr. F. Brandenberg, of Zug, relates a singular instance of idiosyncrasy as to antipyrin. A man who was suffering from acute articular rheumatism, and could not tolerate salicylate of soda, took fifteen grains of antipyrin in powder. About five minutes later there suddenly appeared violent toothache along the whole lower jaw, then headache, an intense "tearing-asunder" pain in the ear and the parts adjoining, with profuse flow of tears and nasal mucus. The symptoms ceased in the reverse order of their appearance, the toothache lasting for three to four hours. To elucidate the matter, Dr. Brandenberg requested the patient, a very intelligent man, to take another dose. The patient consented, but this time took only seven and one-half grains of the drug. In ten minutes, precisely similar symptoms developed, the toothache lasting for about twelve hours. Curiously enough, the articular pain had disappeared almost completely before the appearance of the other symptoms.—*British Med. Journal*, Dec. 15, 1888.

The Anatomical Tubercle.

Dr. William Osler writes as follows in the *Montreal Med. Journal*, Dec., 1888: There have been of late years several very interesting observations upon the common post-mortem wart, or as it was named by Wilks, who first described it, *verruca necrogenica*. It is now very generally regarded as a local tubercle, the result of inoculation. The presence of bacilli has been demonstrated in several instances. The tubercles consist chiefly of granulation tissue, occasionally with giant cells, and with papillomatous outgrowths of the epidermis, which give the tubercle the wart-like character. They are met with in persons who perform many post-mortems, and in those whose business brings them into close contact with animals and animal products. Their occurrence is by no means infrequent. In Germany it is quite common to see the hands of the demonstrators of pathology (and more especially the attendants in the autopsy rooms) disfigured by these structures.

I have myself eight or ten scars from these warts, which I have had at times on my hands during the past fifteen years. They rarely increase in size beyond a quarter of a dollar piece, are seldom painful, and are only unpleasant on account of the disfigurement. In my case they have lasted variable periods, from four or five weeks to eight or nine months. I have usually found them to disappear spontaneously. Thus, the last one I had was the result of accidental inoculation made from a phthisical subject early in November. I persistently refrained from local treatment in order to watch its development. It gradually spread, and after attaining the size of a ten-cent piece remained quiescent, but did not disappear until June. As is often the case, it had several small colonies in its neighborhood. In the treatment of these structures, I have usually found that the oleate of mercury persistently applied with friction causes rapid disappearance.

In Hutchinson's lectures on Lupus, which appeared in the *British Medical Journal* during the early part of this year, the anatomical tubercle is classed as "lupus necrogenicus," and a very good case is made out in favor of placing it among the lupoid affections. He mentions an interesting instance in which a post-mortem wart has persisted for nearly forty years. Although harmless in the majority of instances, there are cases on record, some of which are quoted by Ruhl and Paltauf in their exhaustive article in vol. xiii of *Vierteljahresschrift für Dermatologie und Syphilis*, in which systemic inoculation has resulted from the local sore. Verneuil suggests, in this connection, that the phthisis with which Laennec suffered might possibly be associated with the wound which he received many years before at a post-mortem on a phthisical subject. No doubt the reason why systemic infection is not more frequently observed is owing to the unfavorable soil which the skin offers for tubercular processes.

Formula for Producing Local Anæsthesia.

Dr. J. M. Lewis, of Mexia, Texas, gives the following formula for injection before extracting teeth, in *Daniel's Texas Med. Journal*, Oct., 1888:

℞ Cocaini muriat. . . . . gr. viii
Chloralis hydrat. . . . . gr. v
Acidi carbol. . . . . gtt. iii
Aquæ destil. . . . . f℥ iii
M. Sig. Inject two or three drops into the gum.

Swallowing Sovereigns.

Dr. Siotis reports the case of a patient who had swallowed fifteen sovereigns. He complained of severe pain in the epigastric region. Auscultation revealed the distinct clinking sound of the coins when the patient moved. Purgatives were useless. Pills of opium and belladonna were then administered. The next day three gold pieces were found in the fæces, and a painful cylindrical tumor was detected in the rectum. On the following day four other pieces were expelled, and severe pain was felt in the right iliac fossa. When percussed, this region gave a metallic sound. The remaining gold pieces were shortly afterward expelled, and the patient completely recovered.—*British Med. Journal*, Dec. 22, 1888.

Association of Acting Assistant Surgeons, U. S. Army.

The Annual Meeting of the Association of Acting Assistant Surgeons of the U. S. Army, an announcement of which was published in the REPORTER Nov. 24, will be held in Newport, R. I., Monday, June 24, 1889, at 8 P. M. Members of the Association are cordially invited to read or present papers concerning the history and the welfare of the corps.

Members who intend to be present are requested to notify the Recorder, W. Thornton Parker, M.D., Newport, R. I., at the earliest possible date.

NEWS.

—Dr. Amos Walker, formerly of Philadelphia, died at Doylestown, Pa., January 10, 1889, in the 95th year of his age.

—Several families in Albany, New York, are reported to have been poisoned by eating cheese and pickles. No deaths have occurred.

—Lieutenant Miles, of the United States Steamer Yantic, which recently arrived in New York from Hayti, died of yellow fever January 14.

—Dr. B. F. Kane, Professor of Clinical Medicine and Pathology, Medical Department of the University of California, died Dec. 29, 1888.

—The eleventh public congress of the section in Balneology of the German *Gesellschaft für Heilkunde*, will be held in Berlin in March, 1889.

—Prof. Liebreich announces in the November number of the *Therapeutische Monatshefte* that he has succeeded in producing cocaine by synthesis.

—Dr. Thomas Goodwillie, of Vernon, Vt., died of pneumonia Dec. 22, 1888. He was graduated from the Medical Department of Dartmouth College in 1866.

—Dr. George A. Bodamer has resigned his position as Resident Physician in Chief of the German Hospital, and intends to go abroad for purposes of study and recreation.

—Dr. Nathan Allen, of Lowell, Mass., died Jan. 1, 1889, at the age of 76. He was graduated from Amherst College in 1836, and from the Pennsylvania Medical College in 1841.

—The President of the Board of Health and the Health Officer, of Jacksonville, Florida, have issued bulletins declaring the city of Jacksonville and the county of Duval free from yellow fever and perfectly safe to visit.

—A cable dispatch to the daily papers states that the Royal College of Surgeons of England has passed a vote of censure on Sir Morell Mackenzie for publishing his book on the case of the late Emperor Frederick. The vote was twenty-one to two.

—The number of deaths in Philadelphia last week numbered 360, a decrease of 29 as compared with the same period last year. As usual the number of deaths from diseases of the lungs and bronchi largely predominated, numbering 121 in all. There were 9 deaths from scarlet fever, and 10 from typhoid fever.

—The *New York Med. Journal*, Jan. 12, in its statement of the infectious diseases in New York, gives the following figures for the two weeks ending Jan. 8: Typhoid fever, 29 cases and 11 deaths; scarlet fever, 544 cases and 87 deaths; measles, 809 cases and 35 deaths; diphtheria, 296 cases and 93 deaths.

HUMOR.

A CALL TO ARMS—a wail from a baby at 2 A. M.—*Burlington Free Press.*

EMPEROR WILLIAM has instructed the army physicians not to be afraid of making their treatment Teutonic. — *Pittsburgh Chronicle.*

SURE CURE.—Family Doctor—"Your wife needs outdoor exercise more than anything else." Husband—"But she won't go out. What am I to do?" "Give her plenty of money to shop with."—*New York Weekly.*

MRS. VENEERING—"Really, my dear doctor, you must come to my ball. It is Lucy's coming-out affair, you know, and I shall take no refusal; none at all." Doctor Bygfee—"Well, you see, my dear madam, I am a very busy man. My time is not my own—" Mrs. Veneering—"Say no more. Include the visit in your bill. There, I shall expect you. Good-bye."—*Pittsburg Bulletin.*

SMALL PRACTICE.—Young Doctor—"Yes, I expect that it will go pretty slow when I first open an office until I get started a little." Old Doctor—"Well, you bet it will. Why, when I first hung out my shingle I sat in my office for three months and only had one case." "Whew! That *was* pretty tough, wasn't it? Only *one* case! and what was that a case of?" "A case of instruments."—*Puck.*

OBITUARY.

JOHN J. SINNICKSON, M.D.

Dr. John J. Sinnickson died recently in Salem, N. J. His family is one of the original Swedish families which came to this country in 1638. Dr. Sinnickson was graduated from the University of Pennsylvania, and served in the war with Mexico. He was wounded in battle and remained disabled from his injuries to the end of his life. He was engaged largely in mercantile pursuits.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

THERE IS A PEPSIN

WHICH IS UNIFORMLY ACTIVE, PERMANENT, AND RELIABLE,

IT IS "FAIRCHILD'S."

This Pepsin will not spoil, will not become soft and sticky in the vial, even if left long uncorked.

Fairchild's Pepsin will not "gum up" if dispensed in powders, plain, or with the drugs usually combined with pepsin.

Fairchild's is not a partial peptone, and has none of the well-known characteristics of peptone.

Fairchild's is the pioneer pepsin, it showed the way. It "got there" early.

Its activity has never been exaggerated.

All this time, whilst other manufacturers were still offering the high-dilution saccharated and amylated article, Fairchild's Pepsin was steadily making its way on its merit. Now, no one ventures to ask a hearing for these *placebo-pepsins*.

When physicians now prescribe "pepsin" they mean pepsin—not milk sugar, and pepsin.

All these years, Fairchild's Pepsin was always and everywhere found to do just what was claimed for it—in spite of the attitude, genuine or assumed, which held that all "claims" about pepsin must be taken with a liberal discount.

Every *bona fide* test demonstrated its reliability.

We have never found it necessary to explain or excuse any deficiency or inaction as due to "deteriorated" specimens.

Fairchild's will not disappoint the prescriber under any condition proper for pepsin.

With Such a Record Fairchild's Pepsin is a good one to stand by

FAIRCHILD BROS. & FOSTER,
82 and 84 Fulton St., New York.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

COMMUNICATIONS.

TUBERCULOSIS.[1]

BY J. H. MUSSER, M.D.,
PHILADELPHIA.

Stenographically reported by Wm. H. Morrison, M.D.

My object, Mr. President, in presenting this account of tuberculosis—of tuberculosis in its entirety—is not to announce anything original, even if it were possible, in regard to the subject, but rather to present it as I think the present state of our knowledge warrants us in considering it, and, in the course of the statements which I shall make, to illustrate the various phases of the subject and its various anatomical and clinical points by the citation of some cases which have occurred to me during my study of it.

I regret very much that, for want of time, I shall be unable to present a series of specimens illustrating the various forms of tuberculosis, not only of pulmonary tuberculosis in which I am more especially interested, but also of the other varieties which I shall mention later. I, however, trust that it will not be long before I shall be able to show both macroscopical specimens and microscopical preparations illustrating the various points which will be brought out in the discussion of this subject. My remarks are based largely on the views of the later workers in tuberculosis, and my support of their statements is based upon the autopsies of some seventy cases carefully recorded, which I have made in the Philadelphia Hospital.

In the first place, in order to be precise, I shall state what I mean by the term tuberculosis. Tuberculosis is a specific infectious disease, the phenomena of which are due to the presence, in one or more organs or universally throughout the body, of the tubercle bacillus. Such is the definition warranted by our present knowledge. Whether or not the phenomena of tuberculosis are due to the tubercle bacillus alone, I am unable to say, but there undoubtedly is present in

[1] An address delivered before the Philadelphia County Medical Society, December 26, 1888.

every lesion tubercular in character, sometime in the course of its development, this micro-organism. Just here let me state the varieties of tuberculosis which we are called upon to see. I do not refer alone to pulmonary tuberculosis in all its phases, but in addition, to the so-called joint tuberculosis, the fungous disease of the joints; to the so-called scrofulous disease of the lymphatic glands, the cheesy glands, lymphatic tuberculosis; and also to tuberculosis of the genito-urinary tract, to tuberculosis of the serous membranes, as tubercular pleurisy, tubercular meningitis, and tubercular peritonitis. Then too, included among the forms of tuberculosis, we have the well-known disease, lupus. From recent observations, I have no doubt that this disease is of tubercular origin. Finally to tuberculosis belongs that most interesting general infectious disease, miliary tuberculosis.

A word in regard to tuberculosis of the lungs. I recognize in pulmonary phthisis only one condition, namely, tubercular phthisis. Such has been my experience. This, however, has its varieties. There is in the first place simple tuberculosis of the lungs—the racemose variety of tubercular infiltration; there is the cheesy variety, caseous phthisis, pneumonic phthisis; there is tubercular catarrhal pneumonia, and fibroid phthisis. These are the forms of tuberculosis found in the pulmonary structure.

By a tubercle I mean a specific inflammatory growth characterized by the presence of round cells, epithelioid and giant cells, and in addition by the presence of the specific irritant, the tubercle bacillus. This organism is present in all forms of tuberculosis. In the tubercle itself, it is universally present. The relation of it to the causation of tubercle depends upon a number of causes which I shall endeavor to detail. The bacillus is the specific element of the inflammatory growth, and the tubercle therefore is nothing more than an inflammatory growth characterized by the presence of this specific element. Round cells, lymphoid cells, epithelioid cells and giant cells are frequently found under other circumstances; but in tuberculosis we never find them without also finding the tubercle bacillus. In the tubercular process a tubercle of the histological characters mentioned need not necessarily be present. These inflammations occur without organized tubercle, as in tubercular catarrhal pneumonia. In this, as in all tubercular processes, whether or not a tubercle is found, the tubercle bacillus is present. On account therefore of the universal presence of this organism—for it is found not only in pulmonary tuberculosis, but also in the other forms of tuberculosis which I have detailed—on account of the fact that by the methods comparatively recently introduced by Koch, this organism can be isolated by means of cultures—and it is the only organism that is isolated by the culture process from any tubercular lesion whatsoever; and because by the inoculation of the organism tuberculosis is produced, we are warranted in giving to it the highest etiological prominence.

For these reasons we are warranted in emphasizing the unity of tuberculosis, the common element being the bacillus. Moreever, the organism is found in the products of tuberculosis, as for instance in the sputum, in the pus from caseous glands or from diseased bone, or in the fluids that come in contact with infected centers, such as the urine in tuberculosis of the kidney and the stools in intestinal tuberculosis. It is found here not because the urine is pathogenic, but because the bacillus is washed out by the urine. It is found in all the discharges that arise from the irritation of this organism. When I say that it is found in all the discharges, some limitation must be made; for instance you may tap a tubercular pleurisy and fail to find any bacilli; or, more likely still, a caseous gland will be aspirated, and while we should expect to find the tubercle bacillus in the products of suppuration, this is not always the case, and for two reasons: In the first place, and this is the minimum reason, the bacillus is not abundant in the pus from tubercular lymphatic glands. There is not an excess of growth. In the second place, it is well known that the organism, especially in suppuration, may escape and not be detected by our cultures and staining. It is said that it is more particularly apt to escape in the process of suppuration, and while found in the tissues is not found in the degenerated products. There is, however, this point to prove the specificity of the product, namely, that if you take the product, even where you have failed to find the bacillus, and inoculate with it, tuberculosis is invariably produced, so that by inoculation of the bacillus isolated by culture, or by inoculation of the products of inflammation or by the inoculation of the inflammatory growth itself, tuberculosis is induced. The law is absolute that tuberculosis alone produces tuberculosis and that nothing else whatsoever will do it. An explanation of the fact that the inoculation of products of

inflammation in which the tubercle bacillus may not be found, causes tuberculosis, is said by careful workers in this subject to be found in the presence not of the fully developed bacillus itself, but of the spores of this bacillus.

While therefore a tubercle is nothing more than an ordinary inflammatory growth, the result of the action of the specific irritant differs very much and does not necessarily cause tubercle alone. Thus in tuberculosis, the further process in the development of the disease, or perhaps in the immediate effect of the irritation, is frequently seen in caseation. This is most marked, and it is almost one of the specific elements of tubercular disease. It is true that caseation takes place under other circumstances. It is found, for example, in carcinoma and gumma, but it is especially characteristic of tuberculosis. There is one form in which caseation or caseous necrosis is so common, that it is known as caseous pneumonia or caseous tuberculosis: the cheesy variety of tuberculosis. I can give no explanation for the presence of the change. Coates has recently stated that caseation is so general, so universal in tuberculosis that it may be considered part and parcel of the tubercular process. Another feature of this specific inflammatory growth is its marked tendency to fibroid change. Anyone who has examined the various forms of tuberculosis, and particularly pulmonary tuberculosis, will have often seen this. There is almost constantly a marked tendency in some areas for the occurrence of an overgrowth of connective tissue. This is conservative, and part of the process which leads to healing, which is much more frequent than we generally admit.

I have said that tuberculosis is an infectious disease. That this is so is well known, particularly from the fact that it can be reproduced by inoculation of the tuberculous inflamed mass or its products as I have already pointed out, as for instance serum or sputum from tubercular lesions. As you well know, Tappeiner, long before the discovery of the tubercle bacillus, found that he could set up tuberculosis in animals by the inoculation of sputum from tubercular subjects. The pus from caseous glands, from a suppurating lung or from a pulmonary cavity will also, by inoculation, produce tuberculosis. I will refer later to a further proof of the infectious nature of tuberculosis, as proved by the fact that eating the flesh of tuberculous animals or drinking the milk from tuberculous cows has frequently caused the disease. Moreover, one characteristic which belongs to all forms of infectious disease, obtains also in tuberculosis: I refer to incubation. This is definitely and quite positively proved. It is well known that in tuberculosis artificially produced, the disease arises in from fifteen to twenty days after inoculation of the tubercular matter. The experiments on this point are absolute and final, and cannot be gainsaid. This is proved not only by the experiments of Koch and his fellow-laborers, but even by experiments made before the period of the full knowledge that the tubercle bacillus existed. It was well known that in a definite period after the inoculation of certain materials, tuberculosis would develop.

Not only is this period of incubation shown in the production of tuberculosis artificially, but it is also occasionally seen in the human subject. It has been traced in some epidemics and outbreaks of tuberculosis, where in a definite period after the ingestion of flesh or of milk from diseased animals, tuberculosis has developed. It is, however, very difficult to determine this period of incubation in the human subject, and in fact, if we had not the results of experiments on animals, we should not be warranted, for reasons which I shall refer to further on, in stating that a certain number of days was the period of incubation. Attention has been called by Coates and Woodhead to the fact that in cases of old quiescent tuberculosis, there has been after the occurrence of hemorrhage the involvement of the general system in the course of fifteen to twenty days. After such a hemorrhage, tuberculosis sets up and from that time the progress is rapid. At the autopsies the lesions of general tuberculosis are found and also the lesions of the old, quiescent local disease. Just such a case presented itself in my wards of the Philadelphia Hospital, in the person of a healthy-looking, burly negro who had for a long time been the subject of a cough. There were present the physical signs of a circumscribed pulmonary cavity, but that the disease was not making any inroads upon his health, his condition testified; and that the lung was not generally involved, the physical examination showed. A short time after coming under observation, he had a hemorrhage, and about twenty days after the bleeding fever made its appearance with all of the phenomena of tuberculosis, and in five weeks he died of general tuberculosis, infected by the local disease of the lungs.

If the tubercle bacillus is related to the causation of tuberculosis—I have merely affirmed that it is universally present in the tubercular products—its mode of introduction into the system must be accounted for. It can be introduced by inhalation. Experiments have proved this. There is a fair amount of clinical and experimental evidence, if properly weighed and sifted, to show that by the inhalation of the products of tuberculosis, the disease can be set up. Tappeiner many years ago produced tuberculosis by causing animals to inhale the dried sputum from phthisical patients. There is no doubt that this is a common source of the disease, perhaps more common than we are willing to admit. In hospital wards where there are a large number of cases of tuberculosis, there is no doubt that the air is fully infected. The air in the Philadelphia Hospital at one time was examined by processes which all sanitary experts and others who work in this subject well know, and in some of the wards it was found to have the tubercle bacillus floating freely through it.

The tubercle bacillus is also taken into the system by means of the food. There is no doubt about this, and there is no necessity to cavil about it. The eating of the flesh of animals infected with tuberculosis has frequently caused epidemics of this disease. More especially may it be caused by milk from infected animals.

Here comes up an interesting remark made by Woodhead on this very point, that cases of infantile tuberculosis, and of local epidemics of tuberculosis, have been undoubtedly traced to the use of milk from cows in which there has been tuberculosis. The tuberculosis need not be general in the animal, and hence no general symptoms, for in several instances it was limited to the udder, and thus infected the milk. Not only is the tubercle bacillus found in the tissue of the udder, but also in the milk with the other secretions. Animals, as for instance, pigs that were fed with it, died of tuberculosis, and by staining the fluid, as well as by cultures, the organism was found. Heubermaas, more wonderful still, reports eight cases of infants, infected from their mothers, on account of tubercular mammitis.

Another way in which the tubercle bacillus may enter the system is by absorption. There has recently been sufficient evidence produced to show that by the absorption of the tubercle virus through the skin, the disease may be set up. In all probability caseous glands are thus caused. There is skin irritation, exposure to the tubercle bacilli, and as a result secondary disease of the glands. This is not as positively proved as the other modes of introduction of the poison; but there is strong evidence that it may occur. That we have tuberculosis of the skin is well known, as seen in lupus.

One of the most interesting facts, or series of pathological facts, in regard to tuberculosis, is its method of spreading throughout the system after being introduced. It is of course known that it is locally infective and that it usually extends along the course of the lymphatics, but it is also important to remember, as Coates points out, that tuberculosis is a disease of surfaces and channels, and that the organism, or the products containing this organism are moved about over these surfaces and in that way infection takes place.

If there is tubercular disease anywhere, local infection is very readily seen in the tissues about the lesion. This is particularly seen in phthisis. Around the old lesion—a cavity or caseous mass—a dense area of tubercular infiltration is seen, and then an area of scattered tubercles, more and more separated, and younger and younger, until the healthy zone is reached. Along the course of the lymphatics the disease develops and has often been seen. This is possibly seen more frequently in tabes mesenterica than in any other variety. Even in adults you can often trace from a local area the course of the infection throughout the body. In a case which was under observation some time ago, there was tubercular disease of the lymphatic glands around the bronchi at the root of the lung, the lymphatics coursing toward the pericardium were markedly tuberculous and at the autopsy the disease could thus be readily traced to the pericardium. The pericardium was infected, tubercular pericarditis was set up and the patient died as a result of the enormous pericardial effusion, thus excited. Over and over again this has been seen. Coates, and a number of others, have reported examples in which, from old lesions, which were undoubtedly present, in the mesenteric glands, the tubercular process spread to the remainder of the lymphatic system, to the peritoneum, spreading over the surfaces of the diaphragm, from thence extending to the pleura, and in some instances even to the bronchial lymphatic glands. Subsequently the lung became infected. This is one method of the origin of pulmonary tuberculosis. Koch, Woodhead and others mention such cases, and those

who have made many *post-mortems* have seen old lesions of the bronchial, the cervical and axillary or the mesenteric glands with secondary infection of the lungs or the entire system. In one recorded instance the ulceration extended from a caseous gland into a bronchus and thus the lung was rapidly infected. While the patient had been in ill health for some time, yet the occurrence of general tuberculosis was shown by the acute manifestations, and at the autopsy the lesions were found.

I shall not speak in detail of the different channels through which the disease may extend, but shall for a moment refer to a form which anyone can prove for himself. It is well known that after laryngeal tuberculosis begins, general pulmonary tuberculosis takes place sooner or later, and this readily, because the products of the laryngeal disease are aspirated into different areas of the lung, and thus the pulmonary structure is infected. In the same way the disease may extend throughout the lung. There is, for instance, infection of one apex, and fluids from this area are drawn, by aspiration and the position of the patient, into other parts, which are secondarily involved. As long as consolidation alone is present—there is usually no secondary involvement, and, indeed, if caseation and ulceration do not take place, but on the other hand the opposite process, fibrosis, ensue, there will be no secondary involvement. The occurrence of intestinal tuberculosis following pulmonary tuberculosis is due to the fact that the products of the disease in the lungs are swallowed and thus the intestinal canal is infected. And in a manner similar, tuberculosis of the genito-urinary apparatus is evolved, either from the kidneys to the remainder of the apparatus, or more frequently from a tubercular testicle along the lymphatics to the other strictures.

A word in regard to some interesting evidence as to the manner of general infection of the body from local disease as shown in miliary tuberculosis. For a long time we were unable to explain miliary tuberculosis, and how it was that the organism became infected. While even yet there are many cases of which we can not speak positively, yet the researches of Ponfick, Weigert and Coates leave no doubt that if careful search is made it will be found that the organism has been infected through the thoracic duct from an infecting tubercular mass in any portion of the body or from extension of the tuberculous process to the veins. This latter method is discussed by Weigert. If a careful search is made the origin of the affection can usually be explained. I have seen it once or twice and demonstrated its course once this year and once last year. It is not often that opportunities for studying acute miliary tuberculosis present themselves. Coates explains the occurrence of the disease by involvement of the veins adjacent to or supplying the diseased lymphatic glands and by infection of the system through the blood. We know that the tubercle bacilli are found in the blood and in the spleen, as well as in the infected tissues.

There are a few characteristics of the growth and development of the tubercle bacillus which explain very well the clinical course of tuberculosis, and in studying tuberculosis it is most important to consider them. From a knowledge of these features we know why it is difficult to reckon the period of incubation or the date of first infection; why the disease is one of long duration; why it is so frequently cured, and why it is so difficult to determine the contagiousness of the disease and the relation of predisposing causes—such as sex, age, occupation, climate, etc.—to the origin of the disease. In the first place it is well known that it develops slowly. This is seen in culture preparations. It is also seen when inoculation is performed. It is true that local irritation is set up, but the general development is slow; hence the disease is always of long duration. It is particularly on this account that we are unable to tell when the person has been infected. For instance, I may be exposed to the tuberculous poison now, I may have inhaled the tubercle bacilli in large numbers, but my tissues may not be in a condition to afford a place for their rapid development. There is not epithelial abrasion to admit of the introduction of the bacillus, or there is not that low vitality of the cells which must exist before there can be bacillary growth. But the organism is not readily destroyed. It may find a lodgment, but not a soil for growth. It may, however, retain its vitality for a long period of time, a second peculiarity of its life. It will live for a long time under unfavorable circumstances and for a long period of time remain quiescent. It can not, indeed, be definitely estimated how long this may continue. In scrofulous disease of the glands we know how long the duration of the disease is. I have now under my care a

colored woman who has been under my observation for two years, in whom a long time ago tubercular disease was shown to be present by the discovery of the tubercle bacillus in a section of a gland taken out. The patient is still in fair health. The disease is progressing, but only slowly. This is also illustrated in the case of a man who recently came under my care, from whom a large number of lymphatic glands were removed by Dr. Pancoast in 1876, at the Jefferson clinic. Only the glands on one side were removed. The glands of the other side continued to grow and from the glands of the neck, the disease extended to the bronchial glands, thence to the mesenteric glands. The relation of the different growths, as regards the point of time, was distinctly shown at the autopsy by the characters of the inflammatory growths of the different parts. It could be seen that the older lesions were in the neck.

We have every reason to think that the primary disease was in these glands, from the clinical course of the disease. After slowly increasing in these glandular structures, acute tubercular catarrhal pneumonia developed and then general tubercular disease, tubercular meningitis being the immediate cause of death. This case shows the slowness of the growth and its power of the bacilli to live under ordinary circumstances of human life without destruction, and this fact explains the long duration of all forms of tuberculosis.

Remember too that the duration, as well as the virulence of the disease is influenced by the number of organisms which have been introduced, as has been shown by many and recently by the experiments of Dr. Trudeau. As you know, he has recently published a report of experiments in which, after the introduction of a certain dose, the disease developed in some up to a certain point and in others lasted for a certain period of time. If a larger dose were given, the course was much more rapid, the general infection more acute and more pronounced. Therefore the slowness of growth, and the number of bacilli introduced are all points explaining the duration of the disease.

As is well known, tuberculosis, including pulmonary tuberculosis and all varieties of the disease, is frequently cured or rather gets well. Under ordinary circumstances, tuberculosis tends to heal. Anyone who has followed the course of a large number of autopsies will have frequently seen instances of arrested tuberculosis, not only in the lymphatic glands but in other structures, as in the bones and in the lungs and even in the intestine. Not long ago, Dr. Osler made an autopsy on a patient in whom there were tubercular lesions in the intestine, some of which were progressing, while others were healed, and cicatrices were found.

In regard to the method of healing I shall not speak for want of time, except to say that it is by an overgrowth of connective tissue surrounding the specific inflammatory growth, the tubercular mass itself.

If, as is stated, one-seventh of all deaths are due to phthisis, the number of cases of tuberculosis must be very great, much greater than is generally admitted. Gardner in speaking from his own experience of tabes mesenterica, and also of other forms, says that they are much more prevalent than was formerly admitted. If one-seventh of all deaths are due to tuberculosis, we would almost be warranted in saying that one-fourteenth of the human race are infected with tuberculosis without evil results. In the autopsies made at the Philadelphia Hospital it is surprising to see the almost universal presence of this disease in a more or less active state, in patients dying from other affections, such as Bright's disease or carcinoma. In a patient recently under my care, for instance, who died of carcinoma of the stomach, there were found tubercular foci and ulceration in the lungs, and this observation could be multiplied. An abundance of examples of healed tuberculosis, as the puckered apices and the encapsulated nodules show, are constantly found.

With regard to contagion. I am inclined to the belief that tuberculosis is contagious, but only feebly contagious. And this is due to the peculiar characteristics of the tubercle bacillus itself. The reason why the disease is not more contagious and more prevalent is because the tissues are not in such a state of vitality as to be receptive to the bacillus, or to form a nidus or a soil for its development, and because there are no pathological processes present through which the tubercle bacillus can enter. Just as it is difficult to determine the period of incubation and the manner of introduction of the bacillus, so it is difficult to determine whether or not the disease is contagious. I may be exposed to the tubercular poison and have inhaled quantities of it at a certain period. This may find a resting-place in my lungs or it may have been taken into the lymphatics; and yet my health and the condition of my

bronchioles and alveoli or gland structures may be such that there is nothing whatsoever to encourage the development of the bacillus, and it will remain quiescent. It is difficult to kill the organism. It will remain quiescent for long periods of time under the ordinary conditions of life, and then from one cause or another, as a long period of indigestion, worry, strain, or break-down of any kind, there is lowering of the vitality of the cells sufficient to allow the growth of the micro-organism and then it is that it develops. This period between the reception of the poison and the development of the disease may be so long that we can not positively trace its cause. It may have been forgotten. The predisposing factors just mentioned become operative in this manner.

I shall not enter into a discussion of other phases of this subject. Already sufficient time has been occupied. The prevention of tuberculosis or its treatment will not be spoken of. Practically, however, the treatment consists in prevention or in attending to the wants of the economy so as to prevent cell life of low grade. I have taken up more time than was intended, but the subject is one of such great interest that it is proper to present some conclusions in the manner which I have done. It is true it has been done in a most cursory and rather unscientific manner, and yet I trust I have shown that tuberculosis is an infectious disease of bacillary origin. A strictly scientific method of presentation of the subject has been sacrificed to one that is truthful, and yet at the same time clear, I trust. The evidence has not been presented as forcibly as my convictions are strong on the subject, and yet it seemed advisable to present the truths in a semi-popular manner. If these remarks are sufficiently clear and earnest to interest and arouse you all, I am content.

N. E. corner Locust and Fortieth Streets.

—The *New York Medical Journal*, Dec. 15, says "Away with the cant that anyone can write too well, or draw too well, or speak too well. Boorishness in style is not evidence of intellect, nor slovenly expression the necessary accompaniment of cultivated observation. Such defects are to be deplored. Their meaning goes deep. A university graduate suggests that it should be a point of honor among medical men to write in such form that an educated person can tell what the subject matter is, though not himself an expert in medical lore."

THE IMMEDIATE TREATMENT OF FRACTURES OF THE EXTREMITIES.

BY ERNEST C. HELM, M.D.,
BELOIT, WIS.

All surgical authorities will agree with Wyeth when he says:

"The great end to be achieved in the *treatment* of fractures is a reduction of the displacement to as near the normal as possible, and the absolute retention of the parts as replaced;" and, as Dr. Edmund Andrews of Chicago, Ill., teaches: "Put the parts in correct position and keep them there." The first part of this advice is usually not very difficult of accomplishment, especially if an anæsthetic is used; so assuming that the bones are in correct position, what is the best way to keep them there?

It is probable that no *perfect* dressing will ever be found, and that a plan advocated now will be antiquated in a few years.

The splint that is safest and most comfortable to the patient, and requires the least care or anxiety on the part of the surgeon, will be a blessing to all concerned.

It seems to me that the splint of the future will be a rigid one, and will be applied at once The primary dressings usually advocated in older, and even the most recent, works on surgery are temporary expedients and makeshifts and are to be used only "*until the swelling has subsided*," and then a rigid apparatus is to be used. This method is all right if the patient lives at a great distance, but in hospital, or where the patient can be seen frequently, for a few days, a splint can safely be used which would absolutely retain the parts as replaced. This fear of swelling is a great bugbear to most young physicians, and therefore with the dread of constriction and mortification before them, temporary dressings are used until swelling has subsided. The patient's sufferings are greatly increased, the provisional callus is much greater, and the cure less rapid and satisfactory than it would be if an immediate fixed splint had been applied.

When the patient has not been seen until the swelling has become great, the surgeon may be forced to use temporary expedients; but if he is seen early, or before there is great swelling, a firmly yet smoothly applied fixed dressing, extending from near the tip of the extremity to well above the seat of fracture would hold the parts as replaced, and moreover, by affording firm

and even support of the tissues, would prevent much swelling. The fragments being immovable, there could be very little callus, and repair would be rapid and uninterrupted. Swelling usually results from an uneven or tight dressing, and from not extending splint (or at least a bandage) well down toward the tips of the extremities. Levis's splints, strengthened by gypsum, have proved very satisfactory in my hands. The Levis splints being moulded to the shape of the limb, and being very light and strong, aid greatly in retaining the limb in proper position while the plaster is "setting."

There are two great objections to plaster of Paris alone: First, while the plaster is "setting," the limb has no support except the hands of the assistant, which often cannot keep the parts exactly as placed; second, the hands, and especially the fingers, deeply indent the soft plaster and make corresponding ridges on the inside of the cast, which may become very painful to the patient.

The use of the Levis splint with the gypsum obviates both of these difficulties. The objections to the perforated tin splints alone are that they are not rigid enough, and are rather short. But as they are strong and light, their conjoined use with plaster of Paris renders the latter lighter than it would be without them, as less plaster is required to obtain the needed firmness. There is nothing new in my mode of application, which is to apply a well-padded Levis splint to the adjusted fracture, securing it there by a few turns of a roller bandage; then to wrap the limb and splint in a thin layer of cotton, and apply plaster-of-Paris bandages until the desired firmness is obtained. The plaster extends from the base of the phalanges to considerably above the fracture —above the next upper joint if possible. In fractures of the femur or the humerus the gypsum may not have to extend so far down, but then a bandage would have to be used from the base of the phalanges to the plaster, otherwise swelling would ensue.

The patient will have to be seen in a few hours, and if there is little pain, and the fingers or toes, as the case may be, are not cold or blue or swollen—in other words if the circulation is good in them—the patient may be left. It is well to see him several times during the first four days, and to instruct the nurse to call you instantly if there is much pain or swelling. After four days the patient will require little care. Should pain or swelling be great the bandage can be loosened by a longitudinal incision, and a roller applied. This in itself is a fine and quite rigid dressing. Usually, however, the circulation continues good and the patient comfortable.

The advantages of immediate fixed dressings are so obvious that I need not refer to them here. Their dangers have been greatly exaggerated, for if carefully and intelligently watched for the first few days, they are probably safer than any other. As there is little if any movement, there is much less provisional callus, and consequently, if the fracture is near or involves a joint, there will be less danger of anchylosis; though in joint injuries the splint should be removed and passive motion practised as soon as it is deemed safe. I could cite many cases in which this mode of treatment has been used, but will mention only four or five very briefly.

On July 4, 1888, my brother, Dr. A. C. Helm, and I treated a case of Pott's fracture in the manner indicated. It was a railroad injury and there was great displacement, yet the recovery was almost painless and both rapid and uninterrupted. A few days later we treated a fracture of both bones of the forearm in the same manner, with very satisfactory results. This was originally a case of green-stick fracture, but both bones were broken in the attempt to straighten them. A fracture of the femur in a child three years old was easily treated by this method of dressing, and so was a fracture of both bones of the leg, just below the middle.

An old man last February broke his arm at the elbow, the fracture extending through the humerus just above both condyles, splitting between them into the joint. The method of treatment I have described was as satisfactory here as in the other instances. In none of these cases, indeed, did the dressings have to be loosened or changed on account of swelling.

Whether this plan meets the approval of the readers of the MEDICAL AND SURGICAL REPORTER or not, I can only say that in my hands it has not disappointed me once, but has always exceeded my most sanguine expectations. I hope others who may have adopted the same method of treatment will give the result of their experience.

—Typhoid fever is said to be prevalent in Vienna. There were 10 cases in June, 32 in November, and 40 up to the 17th of December. This shows an increase of about 50 per cent. over the total for 1887.

THE TURKISH BATH AND ITS USE AS A THERAPEUTIC AGENT.[1]

BY A. HAMILTON DEEKENS,
UNIVERSITY OF PENNSYLVANIA.

The subject I wish to bring before you this evening is one in regard to which, as future physicians, I think we should be to a certain extent familiar, *viz:* "The Turkish Bath and its use as a Therapeutic Agent." A certain amount of knowledge of this now popular mode of treatment is demanded both in our own and our patients' interests. The attention of the laity has been attracted, during recent years, toward the Turkish bath, as a means of cure for various disordered conditions of both body and mind; and they naturally turn to the physician for his professional opinion on the subject, and it is but fair to them, that he should study its merits and demerits, according to his best judgment, and give his patient the benefit of any good there may be in this system.

Until quite recently, most people, including the majority of physicians, have had exceedingly erroneous and exaggerated ideas concerning the Turkish bath, and have conjured up the most frightful visions of the barbarities and tortures the poor victim underwent, who dared enter the portals of this relic of heathenism. No doubt many of these ideas originated in the writings of various humorists—of Mark Twain, for instance, who, in his inimitable book "The Innocents Abroad," gives a vivid description of the tortures he underwent in this Purgatorial region, winding up with his being almost flayed alive with the jack-plane, as he facetiously terms the shampooing brush.

It is true, that when first introduced into England and this country, too much physical energy was occasionally expended on the devotee of the bath; but this, with many other ignorant and unnecessary customs, has almost entirely disappeared, and in modern well-conducted bathing-establishments, everything is carried out according to the most approved anatomical and physiological principles.

The Turkish bath is no new invention. It is as old as the human race. It has been found in all climes and ages, and in every grade of social condition. It is one of the most ancient therapeutic agents of which we have any record. *Heat is its vital* principle. Most nations of the world have recognized this fact. The greater part of Europe used the Turkish bath in one form or other; even the Indians of America were familiar with its application. The ancient Phœnicians used the bath daily, as did also the Greeks. The Romans received the idea from the Greeks, and thus originated the famous Roman baths. When Constantine founded Constantinople he took with him the system so general in Rome, and constructed baths which were among the most magnificent structures in the world, and thus they came to be called Turkish baths.

Our modern so-called Turkish bath, however, would be more appropriately named the "Anglo-American" bath, as to this country and to England belongs the honor of having first introduced the dry air system. Dr. Barton, of England, was the first to discover that the real value of the bath lay in its heat, and was the first to put this discovery to a practical use. He built the first bath ever constructed on the dry air principle, at St. Anne's on the Hill, near Blarney, in Ireland, in 1856. Mr. Urquahart, who has written a well-known book on the Turkish bath, was the first to introduce this system into England, and we are indebted to Dr. Sheppard, of New York, for its first appearance in America. He erected a bath on Laight St., New York City, in 1862. In Ireland, even at the present time, are to be found "sweat-houses," as they are called, the use of which has not entirely died out, and which stand as heirlooms of an ancient people, who in their simple and practical way knew more of the hygienic conditions of life than most of us, in this scientific age, find it possible to put in practice.

One of the national characteristics of the Finlanders of Northern Europe was their constant use of heat, as a means of health, and their manner of using it. Nearly every peasant had a small private bath-house, for his own immediate use. It consisted of one small chamber, in the innermost part of which was placed a pile of stones, which were heated until they became red hot, then a stream of water was directed on them, and the Finn luxuriated in a true Russian or vapor bath. Their power of endurance of heat was wonderful. They would remain in a moist atmosphere at a temperature of from 130° to 150°, for half an hour or more at a time, at the same time going through a system of rubbing, and lashing every part of their bodies with birch twigs, until they

[1] A paper read before the D. Hayes Agnew Surgical Society of the University of Pennsylvania.

presented a very raw appearance. In the winter season, they would frequently go out of the bath in a perfectly nude state, and roll in the snow, when the thermometer stood at 20° or 30° below zero. These hardy natives claim that their strength is recruited as much by the hot vapor baths as by rest and sleep, and such a thing as gout or rheumatism was unknown among them. I do not think, however, that I should advocate their form of bathing, as it would scarcely be suited to the American constitution.

To give you a general idea as to the proper manner of taking a Turkish bath, I will describe the different stages of the process, as carried out in our better class of bathing-establishments. The bather first registers his name and pays his fee, one dollar is the usual price, with half rates to physicians at most places; the bather's valuables are checked and deposited in a safe and the bather is shown to a private dressing-room, where he disrobes and arrays himself in a sheet, after which he is conducted by an attendant through the vestibule to the *tepidarium*. Here a sheet is spread over a reclining chair and the bather takes his place in it. The temperature of this room usually varies from about 110° to 120° or 125°. The air, although so much above summer heat, is not oppressive to most persons, and, owing to good ventilation, it is delightfully pure and soothing. Here the bather remains for a variable length of time, according to his feelings, stretching out his limbs in comfort and allowing care and anxiety to drift from his mind. After being thoroughly heated here, the bather next enters the *sudatorium*. This is a large, well-lighted and well-ventilated room with a temperature of from 140°—160°. Here the flow of perspiration, which began in the *tepidarium*, increases and some of the pleasantest features of the bath are experienced. To give you some idea of the effects of this stage of the proceedings I cannot do better than to describe the sensations as told by Prof. Erasmus Wilson, who is an ardent advocate of the bath.

He says: "The air is clear, no vapory mists. It is fresh, for there is a free circulation of air through the room, and how marvellously soothing! All care, all trouble, all anxiety, all memory of the external world and its miserable littleness is chased from our mind; our thoughts are absorbed in rapturous contemplation of the delights of the new world, the Paradise into which we have just been admitted. The tyrant *Pain!* even loses his miscreant power. The *toothache*, where is it gone? The *headache* disappears, the *spasm* no longer abides, the grinding aches of craving appetite, the pang of *neuralgia*, of *rheumatism*, of *gout*, all have fled, for this is the region where the suffering find a soothing relief from all their torments, and over the door, is it not written, *This is the Calidarium, pain* enters not here."

The temperature of this room is sufficient to secure all needed physiological effects, but for certain diseased conditions a still higher temperature is needed, and for this purpose most establishments have a room with a temperature range of from 200°—250°, this is the so called "*Torridorium*," and although the heat is not sufficient to kill bacteria, it undoubtedly has a specific action on various morbid diatheses, and it is at this temperature that some of the best results of the bath have been attained.

The next move is to the shampooing-room, where the bather stretches out on a marble slab, and gives himself up into the hands of a manipulator, who effectually rubs and kneads, squeezes and percusses, wrings and manipulates his skin until the effete matter and worn out *débris* which has been brought to the surface by the opening and flooding of the pores forms in rolls upon his surface and is rapidly washed away. The process generally removes from one to three pounds of superfluous matter which had been clogging up the system. Shampooing is not the joint-cracking, neck-snapping and generally painful operation which so many imagine it to be. On the contrary, it is a thoroughly pleasant and enjoyable part of the programme, and a skilfull operator soon learns to graduate his muscular force to the requirements of the patient. After the manipulation is over, the bather is led to a shower bath, and thoroughly rinsed off with water at first warm and gradually made cooler, and then allowed the choice of either taking a plunge in a tank of cold water, large enough to swim in, or of first taking the Russian part of the bath, which consists in staying for awhile in a small room filled with hot steam, and following this with the cold plunge. It is not necessary to take the plunge at all, and the bather may merely cool off his body in order to avoid taking a cold when he goes out. After a brisk rub down the bather proceeds, enveloped in a sheet, to the *Frigidarium* or cooling room, where, resting on an easy couch and sipping a cup of coffee, he gradually dozes off into a refreshing slumber, where, in the words

of Bayard Taylor, "mind and body are drowned in delicious rest, and we no longer remember what we are; for gently sleep steals upon our senses; as gently the clouds dissipate, and we are born again into the world, and walk forth instinct with a new life."

The indications for the use of the Turkish bath are numerous, both as a prophylactic and as a means of cure. Physicians of eminence, both in this country and in Europe, have testified repeatedly as to its value in various ailments and diseased habits of body. I cannot give you a better idea of its usefulness in disease than to quote you a few of their public opinions on the subject.

Dr. Austin Flint says that, as a remedy for sleeplessness, it is better than bromides, chloral, or opiates. Dr. Lewis Sayre says that when the medical profession arrives at a thorough knowledge of the value of hot air baths, they will prescribe them more frequently, and medicines less, and be of more service to their patients. Dr. L. W. Thudichum, of London, thinks the Turkish bath, the most powerful and certain, and at the same time the safest and most agreeable therapeutic agent in existence. He says one can remove as much of the poisonous and effete matter from the body in one hour in a Turkish bath as can be removed by other means in twenty-four hours, and that it is a common experience, that persons who have been liable every winter to attacks of catarrh, bronchitis or neuralgia, acquire an almost perfect immunity by the regular use of the bath. Sir Benjamin Brodie, M.D., of London, says it is of great use in dyspeptic and gouty diatheses, and to those who lead inactive or sedentary lives. Professor Erasmus Wilson, says that in the Turkish bath the skin acquires color, freshness, firmness and elasticity; it loses the muddy and faded hues of ill-health, and the parched and wrinkled aspect of infirmity and age; and that it procures for the habitual bather exercise, health and life. Sir John Fife, M.D., of Edinburgh, who was the first to establish a bath in connection with a hospital, at the great Newcastle Infirmary, says that its effects are most remarkable in obviating disorders and palliating diseases of the liver and kidneys, the passage of gall stones and the relief of kidney obstructions often occurring almost immediately after the use of the bath.

I could give you much other testimony of the same character; but these quotations are sufficient to show you that many of the leading physicians of the world are firm believers in the therapeutic value of this agent. As far as my own personal experience and observation go, the indications for the use of the bath, seem to point most strongly to its use as a diaphoretic, a general tonic, and a febrifuge. It is roughly estimated that there are seven million pores opening on the surface of the skin. These are the vent holes, or sluice gates, for over twenty-five miles of drainage. To insure health, it is necessary that the greater part of this system of drainage should be in proper working order. If the sluice gates are blocked up, the waste matter must find an outlet in some other quarter, and naturally it permeates the tissues of the body, enters the blood current and produces diseases of various kinds. The Turkish bath, by opening the pores, by flushing and allowing free egress to this deleterious matter, cleanses the blood from impurities, gives an impetus to the circulation, and invigorates the entire organism. It is one of the best remedies I know of for relieving a "general cold," and it acts well as a mild febrifuge. I have reduced my own temperature a degree and a half when suffering with a slight fever, by a stay of about 20 minutes in the hot room. There are many instances on record, of ladies who on first entering the bath would not sweat below their waists, and who, by continuing its use, have procured a uniform opening and cleansing of the pores, followed by a general improvement of health, and disappearance of nervous and dyspeptic symptoms. In cases of chronic eczema, some most happy results have been reported from the continuous use of the Turkish bath. Unlike many rules the Turkish bath works both ways: it will reduce superfluous tissue, and, by its action in restoring the system to a normal condition, it will also increase the bodily weight. If time permitted, I could give many more instances of the remedial power of this great therapeutic agent, but I hope I have said sufficient to give you an idea of its power for good when rightly used under the directions of a competent medical adviser.

—The *Western Med. Reporter*, Dec., 1888, says that in a recent suit the Supreme Court of Indiana decided that unless damages are collected during the lifetime of the physician, they cannot be collected. No action for damages in a malpractice suit can be maintained after the death of the party sued.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, January 3, 1889.

The President, Thomas M. Drysdale, M.D., in the chair.

Dr. Parvin presented the

Sexual Organs of a Young Girl,

and said that they are among several which he procured in Munich last summer for the purpose of teaching students practically many of the operations upon such organs by the method proposed and pursued by Prof. Winckel. His method is as follows: The organs being properly fastened within and upon Schultze's obstetric phantom, many of the more common operations can be done by the student as upon the living subject. This much was said to explain why he had no history of the subject from which the specimen was taken. In the specimen there is a very perfect annular hymen, one of the rarer forms of this structure, and its borders are quite regularly dentated. The bladder apparently has its walls somewhat thickened, though probably not really; but certainly they seem very thick in comparison with the uterine walls. These latter are so thin that there is in this regard a hypoplasia of the uterus, and thus a uterus membranaceus; but the organ in length and breadth seems fairly developed.

Dr. Parvin also presented

An Obstetrical Manikin.

He had the obstetric phantom made in Munich; it represents a design he had entertained for many years, in fact since the beginning of his obstetric teaching. He wished a complete human form, which could be put in the different positions a woman occupies in labor—natural, manual, and instrumental. The joints are sufficiently mobile to permit the model to be placed on the side or on the back, the limbs put in any position desired. The pelvis is of iron, covered with leather and has a movable coccyx; while the external parts are made of rubber which will dilate so as to admit the passage of a fœtus. The abdominal cavity is ample for the introduction of two fœtuses. One or both may be included in the rubber uterus designed by Prof. Winckel, and thus placed in that cavity. For the suggestion of a cast-iron pelvis, a model of the best one found in the Museum of the Munich *Frauenklinik*, I am indebted to Dr. J. Clifton Edgar, of N. Y., then a resident obstetrician in the *Klinik*. Dr. Edgar, who remained in Munich several weeks after I left, during his stay superintended the work, and doubtless I am indebted to his intelligent supervision, suggestion and direction for the successful manner in which the workman carried out the original design. The model will be useful in gynæcological as well as in obstetric teaching, in that the different positions in which the patient is placed in examinations and in operations can be readily and plainly illustrated. The only addition which it seems to me at present might be usefully made is a rubber abdominal wall, similar to that of Budin's well-known obstetric manikin.

Dr. J. C. Da Costa did not think that annular hymen is so very rare. He had seen some cases and among them one that was very marked. The woman had been married some two years, had been pregnant and had aborted at four or five months. Coitus was excessively painful both to the husband and to the wife, and in the wife was frequently followed by attacks resembling epilepsy. The hymen was annular, smooth, unbroken and elastic, grasping the finger when introduced, like a firm rubber ring. Cutting the hymen cured all the trouble, both of husband and wife.

Dr. Kelly remarked that the condition of the hymen is a subject of much interest, about which many erroneous views prevail. It was by no means uniformly ruptured by coitus. In other cases coitus alone was as capable as numerous pregnancies of obliterating all traces of the hymen. He had made many observations and careful drawings of a number of cases, which showed a definite relation between a certain condition of the hymen and the severity of a preceding labor; that is, when the vaginal outlet has been broken down, with extensive laceration, the hymen remained *intact* except at the split posteriorly, being saved by the vaginal tear. On the contrary, the surest way of thoroughly destroying the integrity of the hymen is the equable, all-around dilatation of a *normal* labor. In a forceps case, examined some months after labor, the hymen, elsewhere intact, was as cleanly cut into halves as a lacerated cervix. It is unquestionably, as Budin has shown, the pointing terminus of the vaginal canal.

Dr. B. C. Hirst showed a specimen of

Endometritis Gravidarum Polyposa

from the University Museum. There are in the Museum two other examples of the same condition, one recently contributed by Dr. R. Deaver, of Germantown. In the last case the embryo was certainly not over three weeks old; the ovum corresponded to the third month and had been retained in the uterus some six months after the death of the embryo. They are all very good specimens of a very rare disease.

He also showed a

Pregnant Uterus

removed from a woman with chronic nephritis, who died suddenly from apoplexy within three months of term. She had been blind for three weeks before her admission to the hospital, and was œdematous in face and extremities. As soon as his attention was called to the case, he ordered premature labor to be induced, but before this could be done the woman died. The uterus showed on abdominal palpation an apparent right lateral version. On opening the abdomen this was seen to be due to the attitude of the fœtus—vertex presentation, L. O. A. The uterine body extended equally to both sides of the median line, but had not the pyriform shape supposed to be characteristic of the pregnant organ. It was irregularly triangular in form, the base of the figure being to the right side, the apex to the left. This would give one the impression on abdominal palpation of right lateral version, from the fact that the highest point of the uterine fundus was to the right side; but this point corresponded to that angle of the uterine cavity on which lay the trunk and extremities of the fœtus.

Dr. Hirst then read the following:

M. M., 39 years old, widow; has had four children; youngest six years old. Six weeks ago the patient attempted to lift a heavy weight, and was immediately seized with sharp pains in the left groin. This occurred just at the commencement of a menstrual flow, which was unusually profuse and painful. The bleeding had in fact continued until the present time (Nov. 8). On this day the woman came by a rather long horse-car journey to the Philadelphia Hospital, to visit her daughter, a patient in the wards; in the hospital she was suddenly seized with great pain and sank to the ground from weakness. She was carried to the medical wards where an examination showed some form of pelvic or abdominal tumor. She was consequently transferred to the gynecological floor. A vaginal examination showed a mass of considerable extent to the left of the uterus, and apparently a cystic tumor in Douglas's pouch. Laparotomy was done the next morning. As soon as the peritoneum was cut through, a large quantity of dark-colored blood welled out of the opening. The incision was enlarged, the intestines turned out and wrapped in warm towels, a pint or more of blood sponged out, and a careful examination made by inspection and touch. The left broad ligament was distended by a tumor, made up, as far as he could tell, of clotted blood; near the uterus there was a ragged opening into which he could put the tip of his little finger. During the half-hour the abdomen remained open there was no hemorrhage from this spot, and had evidently been none recently, for there was no fresh blood in the abdominal cavity. His diagnosis, naturally enough, was ruptured tubal pregnancy. As the embryo, if one existed, was too small to give future trouble, and would be absorbed, he simply cleaned the abdominal cavity, picked adherent clots off the intestines and closed the wound without drainage. The convalescence was entirely favorable. He has been inclined since to alter the diagnosis. The woman, on close questioning, absolutely denied the possibility of impregnation. This fact, together with the history of great muscular effort at the beginning of a menstrual period, and the subsequent behavior of the patient, would naturally suggest the possibility of a rupture of a blood-vessel in the broad ligament. The acute attack of pain and weakness two days before the operation might be explained by a rupture of the peritoneal covering of the effused blood, with an escape of clots and a fresh hemorrhage into the peritoneal cavity.

The following officers were then elected: *President*, Theophilus Parvin, M.D.; *Vice Presidents*, W. H. H. Githens, M.D., and J. C. DaCosta, M.D.; *Secretary*, J. M. Baldy, M.D.; *Treasurer*, Alfred Whelen, M.D.

—A chemist named Halffpap, who practised medicine under cover of a fictitious American diploma, is said by the *Bulletin Medical*, Dec. 30, 1888, to have been sentenced to imprisonment for two years on the charge of homicide. It seems that he prescribed for an infant two months old, suffering with convulsions, one-sixth of a grain of morphine, to be repeated every two hours.

NEW YORK ACADEMY OF MEDICINE.

Meeting of January 3, 1889.

The President, A. JACOBI, M.D., in the Chair.

The annual reports of officers and committees were read, and an oil portrait of the late Dr. Samuel Purdy, was accepted with thanks. Dr. John C. Peters read a memorial of him.

DR. MALCOLM MCLEAN read a paper on

Intra-Uterine Cry after Expulsion of the Waters,

in response to the President's call for the narration of interesting cases. He stated that in August last he was asked to assist Dr. Tracy in delivering a woman at term. Dr. McLean had attended her in four previous normal confinements. On this occasion the occiput was in the posterior position, and while he was trying to rotate the head forward with his hand the nurse drew the patient into a hollow in the bed, whereupon the abdominal organs receded from the pelvis, air rushed into the vagina and uterus, and immediately the child began to cry. The crying continued while he rotated the head, applied the forceps, and extracted, or during about five minutes. It was somewhat remarkable that material was not insufflated, interfering with breathing. The case, he believed, was unique.

The following named members were elected to office: *President*, Dr. A. L. Loomis; *Vice-President*, Dr. D. B. St. John Roosa; *Recording Secretary*, Dr. A. M. Jacobus; *Corresponding Secretary*, Dr. M. A. Starr; *Treasurer*, Dr. O. B. Douglas; *Trustee*, Dr. A. Jacobi; *Treasurer for the Trustees*, Dr. F. A. Castle; *Member of Committee on Admissions*, Dr. Robert Abbe; *Member of Committee on Library*, Dr. E. S. Peck. Five delegates were elected to the State Medical Society.

Stated Meeting, January 17, 1889.

The President, A. JACOBI, M.D., in the Chair.

DR. PAUL GIBIER, of Paris, read a paper entitled:

Yellow Fever; Experimental Researches on its Etiology,

in which he gave a *résumé* of his researches in Florida, instituted under the direction of the government of the French Republic. These experiments were a continuation of certain investigations into the etiology of yellow fever which he had formerly made and reported, once in a paper and again in a lecture, before the Academy of Medicine, Paris.

When he arrived in Jacksonville, Florida, the severity of the epidemic was diminishing. Yet a few cases which he had an opportunity to study and to make bacteriological observations upon were undoubtedly of yellow fever. In one instance especially the symptoms and the pathological lesions were distinctly those of yellow fever. The disease terminated fatally on the fourth day. The intestines contained a large quantity of black liquid, which was alkaline, while the contents of the stomach were acid. This fact is noticeable inasmuch as the bacterium to which he has ascribed the origin of typhoid fever existed only in the intestinal contents; acid fluids would destroy it. In this case, as in all others, this microbe was absent from the blood, liver, spleen, and kidneys. If this microbe is the cause of yellow fever, its absence from the intestines in some cases may be accounted for by the fact, which is well known, that when a culture medium becomes saturated with it its growth stops, and if then another bacterium is introduced it will displace the former. It is his intention, as soon as opportunity presents, to examine the dejecta in a number of cases from the beginning of the disease; and he would not be surprised, he said, if the microbe were present only during the first days of the disease. The theory which he has supported is that yellow fever is an intestinal disease, due to a microbe, and that it must be treated with disinfectants directed to the intestinal tract—such as bichloride of mercury, naphthalin, and tannic acid. The microbes are the origin of certain poisonous ptomaines which enter the circulation and give rise to certain symptoms.

DR. L. D. BULKLEY read a paper on

Unusual Methods of Acquiring Syphilis, with Reports of Cases.

The subject, he said, is a vast one, and could not be fully covered in one paper. He called attention to a few of the innocent methods by which syphilis is acquired, methods which commonly are wholly unsuspected and unprovided against.

When non-venereal methods of acquiring the disease are generally recognized, its dangers will become more apparent and be better guarded against; syphilis

will then also be oftener recognized by the patient and physician when there is no history of venereal exposure, and less stigma will be attached to it. As a result of this, syphilis will be placed where it belongs, among the infectious diseases, and will be placed under the care of health authorities who will aid in stamping out a malady which has caused untold misery both to those guilty and those innocent of sexual transgression.

The relative frequency of the different modes of acquiring the affection is not generally appreciated. Literature contains accounts of dozens of epidemics during which thousands have acquired the disease. There are also reports of cases in which thousands have been infected with the disease in ways hardly suspected before. Fournier has recently declared, from a study of his cases, that in about twenty-five per cent. of all cases of syphilis in females the disease is innocently acquired, and during the discussion of his paper Ricord stated that his experience fully corroborated Fournier's statement.

Dr. Bulkley stated that in looking over the more or less complete records of his cases, numbering something more than 1500, he had found that the larger proportion came under care after the primary sore had disappeared, and in a large number there was no account of the primary lesion or character of the infection. Yet among the 1500 cases notes of extra-genital chancre occurred in 65 instances, or in four and three-tenths per cent. In most of these instances the disease had been acquired in an innocent manner. Thirty-four of the 65 cases were in males and 31 in females. The disease occurred in females in one-third of the whole number of his cases and of these cases it was hereditary in ten per cent.; in the larger share of the rest of the cases the disease seemed to have been acquired in an innocent and unsuspected manner. It was safe to say that in forty per cent. of his cases seen in private practice syphilis had been acquired innocently and undeservedly.

Of his 65 cases of extra-genital chancre, the location of the chancre was on the lip in 30, on the finger in 7, on the breast in 6, on the tonsil in 5, on the tongue in 5, on the cheek in 3, on the chin in 2, on the eyelid in 2, on the nose, ear, hand, forearm, and sacral region in one each.

The unusual methods of acquiring syphilis, or those other than by venereal contact, he classed under three grand groups, which permitted again of numerous subdivisions. The first was syphilis economica, in which, in the ordinary economic or domestic relations, the disease was transmitted innocently. Second, syphilis blephatrophica, in which the disease was acquired by or through infants. Third, syphilis technica, in which it came from body service.

He subdivided syphilis economica into three sub-groups: syphilis by domestic, industrial, and personal transmission. Of domestic transmission, that by means of spoons, forks, knives, jugs, tobacco pipes, is familiar. The author recited one case in his own practice of transmission through the tobacco pipe. Other methods are through wearing apparel, such as shirts and pantaloons. He cited an interesting case in which the chancre was contracted in the sacral region by the wearing of a public bathing suit.

Beds, toilet articles, sponges, toothbrushes, etc., have transmitted the disease. In one of his cases it seemed altogether probable that chancre of the tongue had been caused by pins, which the girl was in the habit of putting into one side of the mouth. It is rather remarkable, he said, that he had failed to find a single authenticated instance of syphilis being acquired in public urinals. Under industrial transmission, he stated that numerous cases had been recorded in which the disease was transmitted through common use of a glass-blower. Not a case had been found in which the disease was attributed to handling paper money. It is commonly supposed laundresses frequently acquire the disease in washing soiled linen of syphilitics, but this mode of transmission has not been proved.

Personal transmission is common, and next to the venereal act, kissing is probably the most common mode of communicating the disease. Dr. Bulkley cited one case in which a man transmitted the disease by kissing the lady to whom he was engaged, and this was the cause of breaking of the engagement; the man soon married another girl, and she acquired the disease in the same manner, that is, by kissing. In one instance a lady gave the disease to a lady friend by kissing.

Many cases have been recorded of transmission of syphilis through nursing and attendance on infants. An instance is recorded in which over forty women and children were infected from one syphilitic child. Individual instances are still common. Of his own 65 cases of extra-genital chancre, 6 were on the breast. Children

sometimes infect attendants and attendants sometimes infect children.

The third great branch, syphilis technica, includes cases in which the operator is the victim; cases in which he, not having the disease, is yet the means of conveying the poison to others, and also includes those in which he is the direct medium. The author cites one instance in which the surgeon acquired a chancre on the finger, and then, notwithstanding his precautions, conveyed syphilis to his wife. There are cases in which, during an examination, the surgeon has got the virus upon the uninjured finger, then scratched the eyelid or other portion of the face, and there a chancre has developed. More than one instance has been recorded in which the patient has projected the virus while coughing, and thus infected the medical attendant. There are a number of instances of syphilis being conveyed to the eye by quacks attempting to remove a foreign body from the eye with the tongue. One of Dr. Bulkley's cases came from tattooing. Cases in which the physician has been the medium of infection were seen in syphilis contracted from vaccination, during ritual circumcision, wetcupping, ordinary surgical operations, in dentistry, etc.

The question of prevention of syphilis is one which should receive the best attention of physicians and of the community.

Dr. S. W. Hubbard cited a case in which an infant acquired syphilis from the nurse when the latter had no lesion on the body, and he expressed the belief that the disease was transmitted through the milk.

Dr. Bulkley, being asked if he thought milk could transmit syphilis, expressed himself in the negative.

The President remarked that milk from the healthy mother is a seeretion, composed mostly of transformed epithelium, while that from one in reduced health is a transudation, composed largely of blood serum and the poisons of the blood which it may carry, and hence it is capable of transmitting syphilis.

—The Empress Augusta has offered, in connection with the German Society of the Red Cross, a prize of $2,500 for the best portable military hospital. The award will be made at an exhibition to be held in Berlin, in June. Prizes will also be given for the best collection of medicines or surgical instruments. All countries are invited to exhibit.

Periscope.

A Few Points in Macewen's Operation for Radical Cure of Hernia.

In a paper on this subject in the *Boston Med. and Surg. Journal*, Dec. 6, 1888, Dr. Herbert L. Burrell says that the indications which have governed him in advising the operation have been the existence of hernia uncontrollable by truss, or rendered painful by truss, or, as in one case, coincident mental depression. In discussing the technique of the operation, he takes it up in sections. He then speaks as follows:

1. The finding of the sac. In performing this operation, the strictest of antiseptic precautions have been attempted, but unfortunately have not always been successfully carried out. The patient having been thoroughly anæsthetized, an incision of two or two and a half inches has been made directly over the external abdominal ring, great care being exercised to bring the incision directly over the middle of the lozenge-shaped opening and running in its direction. Then I have carefully avoided attempting to isolate the different layers which are ordinarily distinguished as covering a hernia. This I have done by having an assistant take a pair of anatomical dissecting forceps, and I have taken another, and then deliberately we have carefully divided every structure for the whole length of the incision that we have met, the assistant carefully grasping the new structure to be divided in the very depth of the incision, and I grasping the tissue directly opposite to him, and then between the two forceps I have divided the elevated layer of tissue. In this way I go on until I meet a rather thick white layer, which on being divided shows that I have entered a cavity, when I know that the sac has been reached. I never attempt to isolate the sac without opening it, for the recognition of the cavity of the sac is its distinguishing point. Therefore the whole attention of the surgeon should be devoted, from the time that he makes the primary incision in the skin, to the finding of the sac. By this means I feel that I have been enabled to save time.

If I cannot readily distinguish the sac, I allow the patient partially to recover from the ether, and very quickly the sac is distended.

2. The isolation of the sac. When I recognize that I am in the sac, from this time on I prepare it for restoration to the abdominal cavity. Should I find it adher-

ent, as so commonly occurs, I fill the sac, through the small opening that I have made in it, with iodoform gauze, distending it, in the same fashion that a mending-ball does the heel of a stocking. Having accomplished this, there is not the slightest difficulty in dissecting out, with the point of a knife or the handle of a scalpel, the distended sac, and separating it from the cord and its accompanying vessels.

When, however, the sac is filled with omentum, implanted directly on and about the testicle, as it was in one of the congenital cases operated upon, one has a difficult, tedious dissection before him to separate it carefully from the testicle and return it to the peritoneal cavity. Occasionally I have had to divide the omentum into various parts and return the carefully secured ends to the peritoneal cavity.

When one has a congenital hernia to deal with, the simplest way, after carefully exposing the sac, is to fill the processus vaginalis with the "iodoform gauze darning-ball," and then to divide the sac into two parts, forming a distinct tunica vaginalis for the testicle, and then sewing up the proximal part of the sac and returning it to the abdominal cavity.

3. The troublesome hemorrhage and the manipulation of the tissues. In the first few cases that I did I had considerable difficulty in identifying the sac, and hence I had once a troublesome hemorrhage from the vessels that accompany the cord. Further, in pulling on the different structures to make them out, I did an amount of damage to their vitality which should be avoided. In two of the cases I feel quite sure that the manipulation of the tissues, especially the dragging of the testicle out of the scrotum, had much to do with the formation of scrotal abscesses. This I believe can be avoided by the "darning-ball of iodoform gauze."

4. The introduction of the sutures. I can only say that I have tried almost all of the different patterns and forms of needles, and have found that I could place the stitches more accurately, and this is really one of the most important points in the whole operation, by a Hagedorn needle in a good needle-holder. I have, after carefully separating the sac the whole length of the inguinal canal and for a half an inch around the intra-abdominal surface of the internal ring, placed a stitch in the very extremity of the sac and transfixed it through and through, and brought it out, after traversing the inguinal canal, through the muscles of the abdomen, pulling up the sac inside the abdomen; the suture pulling up the sac in the same way that a Venetian blind is raised. This suture is not fastened in position until the end of the operation, its protruding extremity being caught in position on the abdominal muscles by a pair of pressure forceps. Then I carefully attempt to restore the valve-like form of the inguinal canal by stitching the conjoined tendon with strong silk or stout catgut to the aponeurotic structures of the transversalis, internal and external oblique. I usually place two, if not three, sutures in position, and as I tie them, have the assistant introduce his finger in the canal, and he can then determine how tightly I bring the parts together, and I run no danger of cutting off the circulation in the cord.

5. Dressing. I always consider that the point where the operation proper is finished and the dressing begins is when I have tied the last suture which closes the inguinal canal. Of course, strictly speaking, this is not the case, but it serves to emphasize the importance of the foregoing procedures.

I have in the last cases closed the opening completely, and have not used any drainage-tube; of course this means that I have had to take a great deal of time in carefully rendering the wound perfectly free from fluids. A thorough and effective flushing at the end of the operation of the whole surface of the wound with 1-1000 corrosive sublimate is, I believe, of the greatest importance. The wound is superficially closed with a continuous catgut suture. The dressing proper is applied as follows: six sterilized gauze pads 6x8x½ are superimposed, covering the wound surface and the scroto-femoral cleft; this is held in place by a carefully applied gauze bandage four inches in width, just enough being used to steady the dressing in place. Over this is laid a piece of Macintosh, with a hole in it large enough for the penis to protrude; then this is covered in by sterilized sheet-wadding.

This is secured in position by a cravat gauze bandage six inches in width and long enough to form a double spica bandage. Over this is placed another piece of Macintosh, with a hole in it for the penis, and this is secured in position by two safety pins laced on either side of the penis and at various other points on the abdomen and thighs as may be found necessary.

6. The question of the necessity of a truss. There can be but little doubt that

the wearing of an ordinary truss after a hernia operation is open to the objection that pressure on cicatricial tissue is usually followed by gradual absorption. I have never felt quite safe in recommending the entire neglect of a truss in the after treatment of this operation, and have therefore been led to use a worsted truss in much the same way that is recommended by Pye. This does not exert any undue pressure on the cicatricial tissue.

These are a few of the points that I have found of interest in performing the operation, and I can only say that they have been derived not alone from my own experience, but from that of my colleagues.

Relation of Acetonuria to Diabetic Coma.

Before the Royal Medical and Chirurgical Society of London, Nov. 27, 1888, Dr. Samuel West read a paper on acetonuria and its relation to diabetic coma, of which the following is an abstract. The relation of acetonuria to diabetic coma had been investigated by experiment and by clinical observation, and this paper was a contribution to the clinical side of the problem. The results of experiment were briefly referred to, and the conclusion to which they led. Clinical observation was for a long time difficult from the want of trustworthy tests. A short account of the chief ones was given: 1. Lieben's iodoform test. 2. Gunning's and Le Nobel's modification of it. 3. Reynolds' test. 4. Legal's test with nitro-prusside of potassium. 5. Le Nobel's modification of it. 6. Penzold's test. Legal's test was found to be the most convenient for use in the urine direct, and Lieben's in the distillate, but this reaction was also obtained if alcohol was present. But if the urine gave Legal's, and the distillate both Legal's and Lieben's tests, the presence of acetone might be accepted. As control experiments two series of convalescent cases were examined. In the first thirty cases, a doubtful Legal's reaction was obtained in three. In the only urine which was distilled neither test was obtained in the distillate. In the second series of about the same number no evidence of acetone was obtained in any. Of non-diabetic patients actually suffering from illnesses at the time of examination, acetone was found in fifteen cases. Acetonuria is therefore very rare in healthy or convalescent persons, but common in various forms of acute and chronic disease. Of diabetic patients fourteen were examined, four being at the time comatose. In some of these cases the examination was continued for many days. The following conclusions were arrived at: 1. Acetonuria is common in diabetics without coma. 2. It is not constantly present in cases of diabetic coma. 3. It varies greatly in the same case from time to time without definite cause. 4. It varies independently of variations in the amount of sugar, specific gravity, etc. 5. It may even disappear when coma develops. The iron reaction shows also no relation either to coma or to acetone. Experiment and clinical observation therefore lead to the same conclusion, viz., that acetone can not be the cause of diabetic coma. Clinical observation, however, seems to show that acetonuria has a clinical value as indicating that the patient is in a more critical condition than when it is absent. The symptoms of diabetic coma depend, in all probability, upon acute intoxication by some substance rapidly generated within the body, but at present unknown. It may be that in the perverted chemical processes which develop it, acetone and the allied body giving the iron reaction are produced, so that the presence of these bodies in the urine may serve as "danger signals."

Dr. Maguire said that acetone is evidently not the poison which produces diabetic coma; nevertheless, the condition is undoubtedly due to the presence of a poison. The liver either may split it up or the kidneys eliminate it, so that, although it may be found in the blood, serious symptoms may not develop. He looks upon the presence of albuminuria as a valuable danger signal when occurring in the course of diabetic coma, its presence being probably due to renal irritation. In every case he has examined, the kidneys have presented extreme parenchymatous inflammation, and such a condition can be brought about by the injection of diacetic ether or acetone into the blood. He thinks that, if albumin is found after acetone has been ascertained to be present, the case is graver than if acetone is found alone.

Dr. Angel Money has on two occasions found hyaline necrosis in the kidneys from cases of diabetic coma. The iron reaction is a sign of danger, and he has never failed to find it when the knee jerk is absent. Albumin is generally present in fatal cases.

Dr. West replied that albumin, like acetone, is by no means a constant phenomenon in fatal cases, and therefore may or may not be a "danger signal."—*Lancet*, Dec. 1, 1888.

The Removal of Hook-Shaped Foreign Bodies.

One of the most acute of American physicians, Dr. Morrill Wyman, of Cambridge, Massachusetts, is reputed to have once relieved a small boy of a fish-hook that he had swallowed by the clever device of slipping a perforated bullet over the line, which fortunately was hanging from the boy's mouth, causing him to swallow the bullet, and then drawing upon the line, the bullet guarding the tissues against injury from the hook during the process of extraction. But the small boy, owing doubtless to the special Providence that watches over him, rarely feeds on fish-hooks, so that Dr. Wyman's expedient, ingenious as it was, is more likely to be handed down in anecdote than to serve as a precedent in actual practice. Most of us are not in pressing need of a device for removing fish-hooks from the stomach—not so much, indeed, as of a trick for enticing hairpins from the urethra—but it happens now and then to almost every practitioner to find himself face to face with the task of disengaging some hook-shaped body that has become imbedded in the tissues. In such a case M. Le Fort, of the Necker Hospital, Paris, lately made use of a procedure which we find detailed in a clinical lecture published in the *Union Médicale* for October 18. The manipulation, however complicated it may seem at first thought when described as *par version, bascule et propulsion* was really very simple. Undoubtedly it has been resorted to by many practitioners, for it would suggest itself at once to a man of ordinary ingenuity; but, as we do not remember to have seen it described in print, we think it may prove of interest to our readers.

The patient was a lad who, nine months before his admission into the hospital, had been struck upon the cheek by a person who held a button-hook in the hand with which the blow was given. The pain of the blow was very great, and the lad at once perceived that the person who had struck him now held only the handle of the button-hook. There was a punctured wound of the cheek, from which a free flow of blood took place, situated in front of the masseter muscle and at the level of the lower teeth. An hour afterward there was considerable swelling of the cheek, and on the following morning, the swelling being persistent and accompanied with rather sharp pain, a pharmacist was consulted, who, as the patient said, "corked up the hole in his cheek." At the end of two or three days the wound had healed and the swelling had subsided, but there was some induration perceptible to the patient, who, however, felt no further pain and no embarrassment of the movements of the jaw. This quiescent state of things continued until about a month before the lad's admission into the hospital, when an inflammatory redness appeared at the site of the wound, and an opening formed from which a little shaft of iron protruded to the extent of about a third of an inch. The hooked extremity was directed backward, and was so engaged in the masseter muscle as not to admit of removal by direct traction without great risk of serious injury. Having enlarged the opening by a slight cut, M. Le Fort depressed the presenting end of the piece of iron and gradually worked it backward until he had reversed its original position. The hooked end now lay forward, and was easily made to emerge from the wound. Reference was made also to a somewhat similar case in which, some years before, M. Le Fort had extracted from a lady's hand a hook-shaped English implement for drawing corks.—*N. Y. Medical Journal*, Dec. 22, 1888.

Abscess of both Testicles Consequent on Urethral and Prostatic Irritation.

Mr. J. Newton Burns reports a case of abscess of both testicles consequent on urethral and prostatic irritation, in the *British Med. Journal*, Nov. 3, 1888. As abscess of the testicle, except in connection with tubercular or scrofulous disease, seems to be rare, he thinks the following notes of abscess of both testicles may be of interest.

Until a week before Mr. Burns saw him, the patient, a hale man 72 years old, had not suffered from any disorder of the genito-urinary apparatus. During that week he had frequency of micturition, and was found by Mr. Burns with bladder distended above the umbilicus. Examination *per rectum* revealed an enlarged and tender prostate. A prostatic catheter was passed with difficulty, and the bladder emptied of over two quarts of smoky urine, mixed toward the end with bright blood and mucus. Catheterization was continued for several days. When the prostatic region became less tender and swollen, and it became possible to pass the ordinary rubber catheter, this was regularly used night and morning by the patient himself. All vesical irritation ceased after washings out with antiseptics, and the patient soon regained health and

strength, though he still continued the use of the rubber catheter.

About a month after Mr. Burns's first visit he received an urgent call, and found the patient in great agony, with his left testicle very much swollen, hot, and tender in the region of the epididymis. At first the enlarged testicle could be distinctly felt at the bottom of the scrotum, but it gradually became indistinguishable from the surrounding infiltrated tissues. The exudation into the skin and tissues overlying the testicle rapidly increased, and in about twenty-four hours the testicle measured twenty inches in circumference.

The usual treatment soon alleviated his distress, and in a few days the measurement was reduced to sixteen and then to twelve inches. Signs of abscess having developed, a free incision was made, and about four drachms of pus and black blood were evacuated. The cavity was then irrigated with water containing a few drops of liniment of iodine, and healed in about ten days. Six weeks later Mr. Burns treated by the same means a similar affection of his right testicle, which, as in the former instance, got well. Both testicles returned to their normal size.

Hill-Climbing for Heart-Disease.

At the seventh Congress for Internal Medicine, held this year at Wiesbaden, an animated discussion took place on Oertel's treatment of chronic diseases of the heart by diet and exercise. Briefly stated, Oertel's aim is to strengthen the heart-muscle by a course of heart-athletics—*e. g.*, hill-climbing, the steepness of the paths being carefully graduated to suit the condition of the patients. In addition, he endeavors to lighten the work of the heart by limiting the amount of fluids supplied to the system and promoting their elimination. He puts great stress on the amelioration of the watery condition of the blood as being an important item in the treatment. In compensatory hypertrophy and dilatation, in acute diseases of the heart-muscle following on sclerosis of the coronary arteries or hæmorrhagic infarct, in myomalacia, and in cases of aneurysm of the heart, the "dietetic-mechanic" method is contra-indicated. In conclusion, Oertel gives the result of three years of his method at Meran, Ischl, Reichenhall, Liebenstein, Abbazia, Baden-Baden, Kreuth, and Wildbad. These results are necessarily valuable, independently of all theories, and are as follows: 1. In cases of fatty heart in elderly people, where there is no perceptible sclerosis of the coronary arteries, and where there is serous plethora, turgid veins, and frequently œdema, the results have been decidedly favorable. 2. Re-establishment of lost compensation and compensatory hypertrophy in valvular lesions, and in impediments of the pulmonary circulation due to diseases of the spinal column. 3. Recovery of the heart-muscle from extensive dilatation (in so far as non-compensatory) following weakness of the heart-muscle, and when caused by heightened intra-cardial blood-pressure due to valve lesions. 4. The best possible balance restored between the arterial and venous systems, decrease of the cyanosis, of the plethora of serum, and of the watery and even œdematous condition of the tissues. 5. Abatement and complete disappearance of the respiratory disturbances.—*Medical Chronicle*, Sept., 1888.

Fœtal Blood at Birth.

Dr. Scherenziss, of Dorpat, has published some interesting observations on the condition of the blood at birth. The specific gravity is, he finds, markedly lower than that of the blood in the adult. The hæmoglobin is also much less than in adult blood, the proportion being 76.8 to 100. The amount of fibrin is only about two-sevenths of that in the blood of the mother. Fœtal blood cannot be analyzed quantitatively by washing with saline solutions, a large part of the constituents of the corpuscles which appear to be in a very loose state of combination, especially the hæmoglobin, going over in the filtrate. Fœtal blood is richer in saline matters than the blood of adults, especially in insoluble salts. The sodium salts are somewhat greater in amount than in the blood of adults, but the potassium salts decidedly less. The sex and the weight of the child appear to have no influence on the quantitative constitution of the blood at birth.—*Lancet*, Nov. 24, 1888.

Frequency of Cancer of the Larynx.

B. Grimme (Inaugural Dissertation, Munich, 1888) states that he has found 15 cases of cancer of the larynx in a total of 13,517 autopsies, a percentage of .11; or, deducting two doubtful cases, .09 per cent. Seven of these fifteen cases were primary, seven secondary, and one doubtful. Epithelial cancer preponderated. The male sex was most frequently affected, in the ages from 40 to 49 and 60 to 69.—*Schmidt's Jahrbücher*, Nov. 15, 1888.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

STATE BOARD OF MEDICAL EXAMINERS.

Probably no single movement of medical progress in our country, within the last decade, has been so marked as the steps taken by several of our States in regard to the requisitions for practising medicine within their boundaries. It is somewhat remarkable that this reform should have commenced, not where one would most naturally have looked for it—in Pennsylvania, New York, or Massachusetts, the old centres of medical instruction—but in some of the more youthful and vigorous members of the Union—Illinois, Ohio, Minnesota, California, and others. These States have set a good example in the legislative enactments which they have made to regulate the practice of the healing art.

For years we have been impressed with the importance of a change in the general methods of licensing practitioners of medicine in this country, simply upon the guarantee afforded by the possession of a *diploma*. Along with many others, we have realized the utter inadequacy of such a certificate. To put the matter in its most favorable light, suppose the diploma to be issued from one of the first-class schools in the land, one where scrupulous care is exercised in the admission of matriculates, where a three years' graded course is required, and where the branches taught even exceed the traditional "seven," is it not a matter of common observation that a student may manage to pass his final examination, and obtain his diploma without any real, practical understanding of his professional duties? If this is true of our best schools, how much worse is the case in those which do not deserve this designation?

As already intimated, we have long been in favor of having a State Board of Examiners to determine the proficiency of the students of the different medical schools of the State, before conferring on them the right to practise medicine. In other words, transferring the licensing power from the professors or instructors in medical schools to an entirely independent Board of qualified and experienced practitioners of medicine.

An obstacle to this plan, often cited, is the difficulty of an amicable arrangement between the various schools of medicine, both as to the manner of appointing the Board of Examiners, and as to the examination of candidates. This difficulty is a very real one and requires wisdom and discretion in dealing with it. Just here, there are certain established principles not to be lost sight of. The law places all medical systems as on a perfect equality, and it cannot be expected to make any distinction between

the graduates of a regular college and those of the homœopathic medical schools. To attempt to exclude candidates from any of the latter from the privileges of examination for a license to practise when their schools are recognized by the very State which creates the Board of Examiners would be unreasonable. The only feasible plan would be to open the examination freely to all who may wish to apply, with the understanding that the subjects for examination would include those taught in the most advanced regular schools.

This is essentially the plan pursued by the Army and Navy Boards. The point to be ascertained is whether the candidates can satisfactorily answer the questions propounded to them by the Board.

A Bill on this subject is now before the Legislature of Pennsylvania. As may be supposed, it has its warm advocates and its strong opponents. But from the powerful testimony brought from those States that have adopted the plan of State Examining Boards as to the uniform good results produced by their operation, both in diminishing the number of incompetent practitioners in the State and in elevating the standard of medicine, we have little doubt of the feasibility of the Act contemplated for our own State, and we hope for its speedy adoption.

TREATMENT OF DIPHTHERIA.

The treatment of diphtheria presents one of the most serious problems which confront the medical man. For years the methods in vogue have been of the most heroic sort; forcible removal of the membrane, active cauterization, and the administration of drugs often most repugnant to the palate and sometimes dangerous to life. Of late there has been a growing tendency to adopt the teaching of Oertel that violent local treatment is useless and dangerous, and less confidence is placed in the virtues of chlorate of potash. Mild local applications like that of lime water or solutions of papayotin have to a great extent taken the place of nitrate of silver and mineral acids, which were once regarded as almost indispensable.

We have already, at different times, called attention in the REPORTER to methods of treating diphtheria which were free from the objections to which some of the older methods are open, and which have already proved of value under our own observation, or that of other practitioners. We now call attention to another which is exceedingly simple, and has proved useful elsewhere.

This method is strongly recommended by Dr. C. Lorey, of Frankfort-on-the-Main, in the *Deutsche med. Wochenschrift*, Nov. 15, 1888, and has been referred to at some length in the letter of our Berlin correspondent, in the REPORTER, Dec. 22, 1888. It consists in insufflation of finely powdered sugar. It is carried out with a tube preferably of glass—charged with pulverized sugar, and armed with a rubber ball, compression of which propels the sugar against the fauces.

Dr. Lorey has used this method in eighty cases, in patients both old and young, and in all forms and grades of the disease. In his hands it has brought about a notable shortening of the duration and limitation of the extent of the disease process, diminution of the foul odor, and loosening and removal of the membrane.

If such results can be obtained with an agent which is absolutely harmless, and by no means unpleasant, the fact deserves careful attention from medical men everywhere, and, in considering it, it is proper to note that Dr. Leroy advises accompanying the local treatment with the administration of a mixture containing from three-quarters of a grain to a grain and a half of apomorphia in three and a half fluid ounces of menstruum, of which a teaspoonful would contain about one-twentieth of a grain. When the acute stage is passed he gives tincture of the chloride of iron with glycerine.

ALEXANDER'S OPERATION.

Shortening the round ligaments, is one of the various methods of treating retroversion, retroflexion, and prolapse of the uterus. It was first done on the living subject by Alexander, and appears to the student both logical and based on correct anatomical principles. Its claim to validity, however, has been more vigorously assailed perhaps than that of any other operative procedure. Both those who deny the importance of versions and flexions, and those who maintain the importance of these displacements, alike contend that by the use of pessaries all needful aid can be rendered, and therefore they condemn the operation as unnecessary. Those who oppose operative procedures in general condemn this operation on account of its supposed dangers, and also, with considerable justice, because operators have sometimes failed to find and draw out the round ligaments. Others have opposed the method on the ground that the principles upon which it is based are wrong; that retroversion, retroflexion, and prolapse of the uterus depend primarily on relaxation of the utero-sacral ligaments, or on relaxation or laceration of the supporting segment of the pelvic floor, or on both; and therefore, since shortening the round ligaments cannot remedy any of these conditions, they assert that a permanent cure cannot be produced by Alexander's operation.

In a conservative and valuable paper read before the Medical Society of the County of New York, Oct. 22, 1888, and abstracted in the REPORTER, Nov. 10, Dr. Mundé discusses the status, indications, limitations, and technique of this operation, and reports his experience with it. He considers that the round ligaments can always be found and drawn out, and the uterus thereby anteverted and elevated, whenever the fundus uteri is not bound down by adhesions, and the ligaments possess their normal play in the inguinal canal.

The principal field for Alexander's operation is in the cure of long-standing cases of retroversion or retroflexion of the uterus, especially when the displacement is associated with descensus, or actual prolapse, of that organ and more or less protrusion of the vaginal walls, together with the bladder and rectum; in other words, when the pelvic floor is either injured or relaxed beyond non-operative restoration. It is taken for granted that treatment by pessaries has been tried and has failed. Alexander's operation is not indicated in cases of backward displacement, or descensus of the womb of moderate degree, as these are comfortably managed by vaginal supporters; adhesions of the uterus absolutely contraindicate the operation. The free, even excessive, mobility of the uterus is considered the one condition justifying it.

If the pelvic floor is intact and the displacement is merely a retroversion or retroflexion with but slight descensus, Dr. Mundé says his experience entitles him to state that the operation of shortening the round ligaments is sufficient to bring about a cure. If the operation is a success, the suspension of the uterus is permanent. When, however, the perineum is destroyed, or the pelvic floor injured or so relaxed as to give no support to the vaginal walls—which in consequence prolapse and drag down the uterus —or when there is complete prolapse of the uterus and vagina, it is necessary to supplement Alexander's operation by an operation to narrow the vagina, and restore the perineum. Under these conditions it seems like trifling with the operation to employ it alone.

Dr. Mundé reports twenty-three operations, of which nineteen were successful; in two, the ligaments were not found, and in two they were both torn off. The nineteen cases remained under observation for periods varying from three months to three and one-half years, and in all but one of these cases the uterus was retained absolutely in the position it occupied at the conclusion of the operation. In one case the fundus dropped slightly backward, but the elevation of the

whole organ was maintained, and the operation was a success. The danger of Alexander's operation is regarded by Dr. Mundé as practically *nil*, if proper antisepsis is maintained.

This paper of Dr. Mundé's is a timely one, pointing out as it does the true field of usefulness for Alexander's operation, a field which is occupied neither by vaginal pessaries, by plastic operations on the vagina and perineum, nor by the newer operation of hysterorrhaphy, or ventro-fixation of the uterus.

PHTHISIS AS A NEUROSIS.

It is somewhat remarkable to find an earnest and industrious student of phthisis, at the present day advocating a theory in regard to its nature which almost entirely—if not quite—ignores the bacillus tuberculosis. We say "almost entirely" because, as we understand Dr. Mays's lectures on Pulmonary Consumption considered as a Neurosis, which were published in the *Therapeutic Gazette*, November 15 and December 15, 1888, he discusses more especially that form of phthisis which begins with a catarrhal inflammation in the alveoli of the lungs, and describes lesions which some students of the subject would say were not really tubercular. We say "if not quite," because we believe he has little faith in the etiological *rôle* very generally attributed by pathologists to the tubercle bacillus, and because his lectures make no distinction between the kind of phthisis to which he refers and any kind in which this bacillus is found.

The substance of his argument is that certain unquestionable neuroses are found associated with phthisis, or alternating with its exacerbations. He describes a number of cases, the histories of which he has collated, which seem to support his view, and claims that it is supported by a study of the nervous element to be found in the fatigue, the aphonia, the dyspnœa, the sweating, the anorexia, the diarrhœa, the hæmoptysis, the œdema and the thoracic pain of phthisis. His conclusion is that a proper interpretation of all the facts shows that pulmonary consumption is a peripheral disease, connected with a depreciation of the whole nervous system caused by a central lesion. He thinks that it is possible for a neurosis of the pneumogastric nerve to give rise to all the lesions generally found in phthisical lungs, although this may not be demonstrable by experiment.

The nearest analogue to the *rationale* of phthisis which he presents, is found, he says, in herpes zoster, in which a neurosis is accompanied by manifestations on the surface, which are characterized by an inflammatory process and destructive lesions.

This theory of phthisis is too startling to be accepted at once; and yet there may be more in it than appears at first sight. It is certainly ingenious, and deserves careful consideration. To our mind the argument of Dr. Mays, while interesting, is by no means conclusive. There can be no question that the nervous system suffers very seriously in phthisis, and that some of its phenomena—such as sweating—are plainly of a neurotic character; but to attribute all of its phenomena to a central nervous disturbance seems to us a step by no means warranted by the evidence adduced.

It is to be hoped that others, who have made consumption the subject of special study, will take up the theory proposed by Dr. Mays, and test it by their own observations; so that, if correct, it may receive the stamp of their approval; and, if incorrect, it may be clearly disproved.

A BILL TO INCREASE the salary of the Surgeon General of the Marine-Hospital service from $4,000 to $5,500 has been introduced into Congress by Senator Cullom. This increase would make the salary equal to that received by the Surgeon General of the army. As the present incumbent of the office of Surgeon General of the Marine-Hospital Service has just entered upon

the office of editor of the *Journal of the Amer. Med. Association*, which has heretofore carried with it a salary of $6,000, the bill referred to, if it should become a law, will make his income a very good one.

THE CASE OF DRS. MCCOY AND WILDMAN.—Drs. McCoy and Wildman, who are practising medicine in Philadelphia and advertising extensively in the daily papers, were formerly located in Chicago, where their certificates were revoked for alleged unprofessional conduct by the Illinois State Board of Health. It seems that Dr. McCoy appealed to the Supreme Court against the decision of the Board, and swore that he had never been served with a notice to appear before the Board, and that, therefore, the revocation of his certificate was illegal. The Court, in the absence of sufficient evidence of service, decided in favor of McCoy. As Wildman's certificate was revoked because of his association with McCoy, the Governor under the circumstances was obliged to reverse the decision of the Board. The Chicago *Medical Standard*, Jan., 1889, says that in the case now pending before the Supreme Court there is reason to believe that a real and not a pseudo-McCoy has been served, and that the glowing miraculous "cures" reported by hypochondriacs will disappear from the advertising pages of the great dailies.

—D. M. Burgess, Sanitary Inspector Marine-Hospital Service, reports to Surgeon-General Hamilton, under date of Jan. 2, that there were 571 deaths in Havana, Cuba, during the month of December. Twenty-six of the deaths are reported to have been caused by yellow fever, 26 by pernicious fever, 1 by paludal fever, 7 by typhoid fever, 2 by small-pox, 1 by diphtheria, 2 by croup, and 3 by glanders. Twenty-six dying of pernicious fever, while during the same time only one died of any other form of paludal fever, leads to the suspicion that pernicious symptoms due to yellow fever may have been confounded with those produced by malarial poison.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

BASHORE'S IMPROVED CLINICAL CHART OF TEMPERATURE, PULSE AND RESPIRATION, DESIGNED FOR DAILY RECORDING OF CASES IN HOSPITAL AND PRIVATE PRACTICE. By HARVEY B. BASHORE, M.D. 50 charts, in tablet form. Size, 8 by 12 inches. Price, 50 cents net. Sold by F. A. Davis, Philadelphia.

These charts are arranged so that the variations in the Temperature, the Pulse, and the Respiration are recorded in spaces provided as in most "temperature sheets." The specimens sent us are not in tablet form; but are detached sheets. Each sheet contains spaces for three weeks' time. They are fairly well printed, but would be more desirable if better paper were used.

QUESTIONS AND ANSWERS ON THE ESSENTIALS OF ANATOMY. By CHARLES B. NANCREDE, M.D., Senior Surgeon to Episcopal Hospital, etc. With 117 illustrations. Small 8vo, pp. 352. Philadelphia: W. B. Saunders, 1888. Price, $1.00.

This volume of "Saunders' Question Compends" is the largest of the series, and one of the most important. Its bulk is partly due to the space occupied by the questions; but principally to the fullness with which the author has treated his subject. It is quite a complete treatise on anatomy, and its descriptions are clear and distinct. Its illustrations are chiefly made from plates used in the first edition of Leidy's Anatomy, and show the marks of use. The printing and binding are good, and the book, as a whole, is creditable to both author and publisher.

QUESTIONS AND ANSWERS ON THE ESSENTIALS OF OBSTETRICS. PREPARED ESPECIALLY FOR STUDENTS OF MEDICINE. By WILLIAM EASTERLY ASHTON, M.D., Demonstrator of Clinical Obstetrics in the Jefferson Medical College, etc. 8vo, pp. xi, 220, with Illustrations. Philadelphia: W. B. Saunders, 1888. Price, $1.00.

The "Essentials of Obstetrics" is the fifth in the series of question compends issued by the same publisher. These compends are intended to be an aid to the student in preparing for examination. Dr. Ashton has written a book which is well adapted to this end; the subject matter is given in clear concise English, and is unusually free from errors of statement, and typographical errors. He has undoubted authority for the principles and practice advocated, but he has not selected his "authority" wisely in all instances. The chief fault of books of this kind is that they give an incomplete representation of the subject. Although Dr. Ashton has not entirely escaped errors of omission, he has done unusually well. As examples of incomplete statement, we note the subjects of the perineum, and Hegar's sign of pregnancy. No one could gain a proper conception of the anatomy and functions of the perineum, or of the technique of Hegar's sign from this book. Also under the head of puerperal septicæmia no mention is made of fevers caused by the absorption of the products of putrefaction within the birth-canal—a large and important class. With some slight exceptions there is only good to be said of this compend as an aid to students preparing for examination.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

189. The Treatment of the Final Stage of Phthisis. By J. H. Musser, M.D., Philadelphia. From the *Medical News*, Oct. 15, 1887. 8 pages.

190. Two Cases of Malignant Endocarditis. By J. H. Musser, M.D., Philadelphia. From the *Transactions of the College of Physicians of Philadelphia*, Third Series, vol. ix. 12 pages.

191. Remarks on Vomiting, Physiological and Clinical. By J. H. Musser, M.D., Philadelphia. From the *Transactions of the Medical Society of the State of Pennsylvania* for 1887. 8 pages.

192. Is the Average Dentist of To-day a Specialist in Medicine? By B. H. Catching, Louisville, Ky. 7 pages.

193. The Great Value of a 0.25D. Cylinder in the Relief of Headache and Eye Pains. By Julian J. Chisolm, M.D., Baltimore, Md. From the *Journal of the Amer. Med. Association*, Oct. 27, 1888. 12 pages.

194. Cataract Extractions, with only the Eye Operated upon closed by Adhesive Strips. By Julian J. Chisolm, M.D., Baltimore, Md. From the *Journal of the Amer. Med. Association*, Nov. 3, 1888. 11 pages.

195. The Preferable Climate for Phthisis. By Charles Denison, M.D., Denver, Colorado. From the *Transactions of the Ninth International Medical Congress*, vol. v. 15 pages.

196. Philosophical Principles of Education and their Scientific Application to the Development and Perfection of Medical Science. By Joseph Jones, M.D., New Orleans, La. 114 pages.

197. Three Successful Cases of Cerebral Surgery. By W. W. Keen, M.D., Philadelphia. From the *American Journal of the Medical Sciences*, Oct. and Nov., 1888. 43 pages.

189. This is an admirable paper giving instructions in regard to the management of patients in the last stages of phthisis, when the hope of a cure has been abandoned. The subject is one which has received little attention in the books, but it is one of the greatest importance. The details mentioned by Dr. Musser are calculated to be of great service at a very trying time.

190. This pamphlet gives the histories of two cases of malignant endocarditis: one somewhat incomplete, derived from notes of the author's father and conversations with him; and the other very full, from observations of the author himself. They are of value as a contribution to the literature of a subject which has only recently received the attention which it deserves.

191. Dr. Musser's paper on vomiting contains an interesting study of the *rationale* of this symptom, illustrated by brief descriptions of a variety of cases in which its cause was traced to obscure conditions, which might easily be overlooked. These descriptions and the comments on the cases are of the most instructive sort, and furnish an admirable example of the habit of careful observation, and intelligent association of the phenomena presented in the practice of medicine.

192. The question which forms the title of Dr. Catching's presidential address before the joint meeting of the American and Southern Dental Associations, in 1888, must be answered in the negative; but he makes a strong plea for a different state of things, and holds that every dentist should be a Doctor of Medicine in order to reach the proper level of scientific attainment, and the greatest measure of success in practice.

193. The contents of this paper have been laid before the readers of the Reporter more than six months ago. Dr. Chisolm has found the use of a weak cylindrical glass of the greatest service in the treatment of the nervous strain and pain caused by low degrees of astigmatism, and urges ophthalmologists to look carefully for the condition for which such glasses are suitable and to apply the remedy which has proved so useful in his experience.

194. The ideas contained in Dr. Chisolm's pamphlet were laid before the readers of the Reporter in an Editorial, in the issue of June 2, 1888. They are sufficiently indicated by the title of his paper, and are now no longer strange to ophthalmologists. Dr. Chisolm has had most excellent results by the method he advocates, and he is naturally a warm defender of it.

195. Dr. Denison is well known as an advocate of the suitability of the climate and other conditions found in Colorado to the treatment of pulmonary consumption. In the present pamphlet he goes very thoroughly over the evidence in favor of his belief, and gives a very interesting statement illustrated by two colored maps of the relative humidity and cloudiness of different parts of the United States. He also discusses briefly a very important phase of the climatic treatment of phthisis, namely, the condition of the patient, which may make removal to a high, dry and cool region wise in one case and very unwise in another.

As a whole, his paper may be commended to the attention of our readers; for serious mistakes are sometimes made in sending phthisical patients away from home, when no possible good can come of the change.

196. Dr. Jones's elaborate and interesting essay on the principles of medical education goes over a great deal of ground, including the nature of the human body and mind, and of the vital principle, as well as the general principles of reasoning and logic. It covers a large extent of time, from that of the earliest Hindoo writers to the present year. Its wide scope can only be indicated here, and it is remarkable how much the author has found to say on the subject.

197. Dr. Keen's paper, which was read at the last meeting of the American Surgical Association, contains a full account of three difficult and successful operations upon the brain. It is written in the clear and attractive style for which the author is well known, and illustrated by admirable wood-cuts. It is much more than a report of the cases described: for the author's account of his operations would serve as an excellent guide to other surgeons even if he had not concluded his paper with a summary of the technique of cerebral surgery.

The paper contained in this pamphlet was regarded as one of the most important scientific features of the recent Congress of American Physicians and Surgeons, and would well repay the careful perusal of all of our readers.

CORRESPONDENCE.

Identity of Scarlatina and Diphtheria.—A Reply.

TO THE EDITOR.

Sir: The article by Dr. Trent, in the REPORTER Jan. 12, on the Identity of Scarlatina and Diphtheria is an interesting and striking contribution to the history of a well-known fact—the frequent coincidence, or close association, precedent or subsequent, of epidemics of scarlatina and of diphtheria. All of us have noticed this close association, and all of us have doubtless seen different members of the same household affected simultaneously, one set with one disease, one with the other; all of us have seen convalescents from one disease contract the other; and some of us have had occasion to question whether the throat affection in a child suffering from scarlatina was simply that of the exanthem, or part of a superimposed diphtheria. The clinical courses of the two diseases differ essentially. But diphtheria does not protect either against scarlet fever or diphtheria, while scarlet fever does protect against scarlet fever, though not against diphtheria; this fact is sufficient in our present state of knowledge to necessitate the maintenance of the distinction between the two diseases. Though their identity has frequently been asserted, this and other considerations have prevented the acceptance of the view.

All that we are justified in asserting from observed facts, is that similar climatic and other conditions, general and local, favor the development of both diseases, and hence they are frequently associated. That some other association underlies this, as well as the association between tonsillitis and rheumatism, and between both of these and scarlatina and diphtheria, is highly probable; but just what it is the bacteriologists or the ptomainologists must be left to discover. Yours truly, S. S. C.

—The *Canadian Practitioner*, Jan., 1888, says that Miss Florence Nightingale has never recovered from the severe strain to which she was subjected in her noble work of nursing during the Crimean war. She is now an invalid from spinal disease, in her seventieth year, and is an inmate of St. Thomas's Hospital, where she will probably end her days, tenderly cared for by the nurses who in that excellent training school are reaping such benefit from the Nightingale fund of $250,000, which was raised in 1858.

NOTES AND COMMENTS.

Clinical Report on Sulphonal.

Dr. William H. Flint, attending physician at the Presbyterian Hospital, New York, in a communication to the *N. Y. Med. Journal*, Dec. 15, 1888, gives the results obtained in the employment of sulphonal in 33 cases. The clinical features upon which special stress was laid in the investigation are: The primary disease of the patient suffering from insomnia; his previous history; the dose of sulphonal administered; the time elapsing after the exhibition of the drug before sleep ensued; the duration of the sleep, its quality, and the after-effects of the remedy.

While he admits that the cases reported above are too few to justify any generalizations regarding the exact indications and effects of sulphonal, they yet offer some interesting corroborative testimony regarding its great hypnotic value already established by earlier observations. The general conclusion which may be drawn from these observations is that sulphonal, even in single doses of 20 or 30 grains, is a safe and, in the main, reliable hypnotic, free from unpleasant concomitant effects, and usually from all undesirable sequelæ. The single objectionable after-effect witnessed by Dr. Flint was moderate somnolence on the morning following the administration of the remedy. In none of the cases was there the slightest derangement of appetite or digestion, and the circulation and respiration have not been appreciably affected at the time of awaking. The cutaneous and renal secretions have neither been increased nor diminished; nausea, vomiting, and constipation have not followed the use of the drug. Several of the cases seem to show that an increase of the original dose is often not required, and that, after a certain time, natural sleep being restored, the sulphonal may be discontinued. This, he says, is the only light thrown by his cases upon the important question as to the possibility of engendering a sulphonal habit or of prejudicially affecting the organism by the continued use of sulphonal. The doctrines that sulphonal is of exceptional value in insomnia occasioned by debility, neurasthenia, and mental perturbation, and that it has no appreciable anodyne properties, receive support from the history of several of these cases. Thus, in one case, the happiest results followed the use of the drug in a destitute, homeless, neurasthenic, and exhausted patient. The same was true in

two cases of hysteria. In six cases the pain of acute rheumatism, of pelvic peritonitis, of chronic rheumatism, of sciatica, and of dysentery was not sufficiently controlled by the remedy to permit of quiet sleep. On the other hand, the pain of splenitis, of cerebral gumma, of pharyngitis, and of alcoholic gastritis, was not of sufficient violence to prevent the patients from sleeping under the influence of sulphonal. The effect of sulphonal was especially fortunate in the cases of those patients who had previously been addicted to the use of opium and of other hypnotic drugs, or were suffering from insomnia due to the withdrawal of these remedies. In four cases of insomnia due to the dyspnœa of cardiac and Bright's disease, sulphonal was powerless to produce sleep, and morphine was alone perfectly adequate to meet the indications. In a case of cardiac dyspnœa, the hydrate of amylene proved fairly successful. In two cases insomnia was occasioned by the harassing cough of pulmonary tuberculosis, but, under the influence of sulphonal, the patients slept better than usual, and although the cough continued during sleep, they were not awakened by it. Sulphonal also rendered excellent services in the insomnia of typhoid fever, as was shown in three cases.

The average length of time at which sleep ensued after the administration of the sulphonal was about an hour. The average duration of sleep was a little over six hours, and success attended the use of the sulphonal in about 82 per cent. of all the trials, and this high average of successes occurred in a series of unselected cases, many of which were plainly unsuitable for experiment with a pure hypnotic.

Danger of White Phosphorus.

At a recent meeting of the Academy of Medicine of Paris, M. Brouardel spoke on the danger of allowing white phosphorus to be employed in the manufacture of matches, and proposed that the Academy should insist that the Government prohibit it absolutely. He considered that all the prophylactic precautions advised would be without effect, inasmuch as the workmen would not follow them, preferring rather to run the risk of getting disease of the jaw than be compelled to adopt an irksome *régime*. He advises the use of red phosphorus, which has proved inoffensive in the different factories in which it has been used. Several members spoke in the same strain, and the proposition of M. Brouardel was unanimously approved.

Primary Sarcoma of the Heart.

At the meeting of the *Aerztlicher Verein zu Hamburg*, July 10, 1888, Dr. Mennig reported a case of primary sarcoma of the heart. The patient was a strong girl, 18 years old, without hereditary taint, and was well up to February 7, 1888. Her health became slowly impaired, and she became affected with loss of appetite, vomiting, dyspnœa, and finally cough with bloody expectoration.

On March 1, great dyspnœa and cyanosis, and a small, irregular and undulating pulse led to the diagnosis of an infarct in the lower lobe of the right lung, and an enormous pericardial exudate. The pericardium was tapped with a fine trocar in the fifth interspace one-finger's breadth from the left border of the sternum, and 9½ ounces of a bloody serous exudate removed. There was at once considerable improvement, which lasted eight days. The temperature during the whole disease continued normal. The pulse, in spite of the use of digitalis, did not fall below 120 after the puncture. On March 4 the presence of an infarct was no longer recognizable. On March 9 there was again great dyspnœa, cyanosis, and a thready pulse. The pericardium was punctured a second time, and within three-quarters of an hour 30 ounces of fluid removed. The pulse then improved, sleep returned, and profuse diuresis set in, and for some days the patient felt comfortable, in spite of the great frequency of the pulse—120 to 140. On March 20, the patient was punctured for the third time, and 24 ounces of fluid removed; on the 25th, the fourth puncture became necessary, and 22½ ounces were removed. Nevertheless dyspnœa and cyanosis did not disappear, œdema occurred, obstinate vomiting set in, and on the 29th of March the patient died in profound exhaustion.

The autopsy disclosed an enormous dilatation of the pericardium, which filled the whole left thorax and had compressed the left lobe of the lung from above downward into a thin leathery mass. The pericardium contained about three pints of a serous fluid, which in its upper layers was clear and yellow, in its lower thick and bloody. The pericardium itself showed no significant changes. The heart was small and flabby. In the anterior wall of the right auricle was a tumor the size of a walnut, which further investigation proved to be a spindle-celled sarcoma. There was nothing abnormal in the right lung and in the abdomen.—*Deutsche med. Wochenschrift*, Dec. 27, 1888.

Salol in Dysentery.

Dr. R. B. McCall writes to the *Medical Brief*, Nov., 1888, that in treating a case of dysentery in a child five years old he tried the methods of treatment which an experience of fifteen years had made familiar; but, as the boy continued to grow worse, he resolved to try salol, which he administered in two-grain doses every three hours. In speaking of the marked and rapid improvement which followed, he says: "In all my experience I never saw the efficiency of a medicine so unmistakably portrayed by characteristic results—the effects following close in the wake of the cause. Dose for first two days was two grains every three hours, increased to three grains, and continued at that as the maximum for three days longer; after which it was given for five days longer in diminishing quantities until left off.

"In about ten days nearly 200 grains were taken, by a child five years old, and that without the least sign of oppression, disturbance of any kind, of stomach, heart or kidneys, or of brain or mind. I believe salol is perfectly safe to be used in suitable doses at any age, and am persuaded from the above case and from a little experience in summer diarrhœas, wherein its influence was unquestionably kindly and effective, that it is destined to be a valuable agent."

Preparations of Sozoiodol in Diseases of the Nose, Throat and Larynx.

Dr. Seifert communicates to the *Münchener med. Wochenschrift*, No. 47, his experience with preparations of sozoiodol in fifty cases. Sozoiodol with talc in the strength of one part to two, or equal parts, is best for application to the mucous membrane of the nose, throat and larnyx. It is preferable in those forms of chronic rhinitis which are accompanied with abnormally profuse secretion. Sozoiodol with sodium in one-half strength was employed, only in the form of insufflations, in tuberculous ulcers of the larynx, with very satisfactory results. The powder adheres firmly to the ulcers and has, on account of its ready solubility, an intense antiseptic effect. But he used most frequently the zinc salt, in those forms of chronic rhinitis which are marked by abnormally small secretion — as isolated forms of hyperplastic rhinitis, and the different forms of atrophic rhinitis. In the first form the secretion was not only made more profuse, but also the mucous membrane of the muscles diminished in bulk in a very striking manner after one or two weeks' treatment, consisting of an insufflation once or twice a day. In atrophic rhinitis the secretion was greatly increased and the fetor obviated. The dry pharyngitis which in most cases coexisted was also considerably improved. In the majority of the patients the strength was one part in ten; in many cases, however, in which this mixture caused disagreeable symptoms, such as violent burning in the nose, headache, and dizziness, the proportion was changed to one part in twelve. The strength must not be greater than one part to seven and one-half. The mercury salt cannot be employed because of its strong corrosive action on mucous membranes.—*Wiener med. Presse*, Dec. 16, 1888.

American Medical Students in Vienna.

Dr. G. C. Simmons, in a letter from Vienna to the *Occidental Medical Times*, Jan., 1889, says that at present among foreigners studying in Vienna, Americans take the lead, outnumbering the English by 100 to 50. The English-speaking students can always be found in company with each other. They go to the same cafés and restaurants, and in general establish the customs of their country. Their patronage is evidently desired, for the cafés subscribe liberally for English and American periodicals. The restaurants announce American dinners, and further, even in the hospital, courses in English are announced. As a consequence of this seeming partiality, an envious feeling has arisen in the minds of Austrian students, and perhaps rightfully. The foreigners crowd the best courses, pay liberally for them, and the poor Austrian student finds them too expensive. This results in the native being often compelled to receive his instruction from inferior teachers and with poor opportunities for clinical study. On the other hand, this liberal feeling for the best courses is becoming a drawback with foreigners, each year the teachers demanding higher honorariums. Such a policy will prove harmful to the success of the Vienna school, for even at this time, it is customary for the American students to stay but a few months, spending the remaining time, and money, in a centre perhaps less famous, but certainly more reasonable in its financial demands. With this single exception, there is no cause for complaint.

Removal of Nasal Polypi During Hypnotism.

The Vienna correspondent of the *Occidental Medical Times*, Jan., 1889, says: Regarding the extirpation of nasal polypi under hypnosis, Professor Schnitzler gives the following details of a case in which the patient had suffered from deafness and disturbances of respiration, owing to obstruction of the nasal passages with polypi. Hypnosis in this case was also produced by an intense light. Several large polypi, and some small ones, were extracted from both nares with the wire snare, and the pedicles touched with the galvano-cautery. The operation lasted about ten minutes, the patient remaining in a deep sleep, similar to that of chloroform narcosis. Upon regaining consciousness she had no recollection of anything that had occurred. She complained of headache for about half an hour. Later on, she was again hypnotized and the mucous membrane of the lower and middle fossæ of the nose was thoroughly cauterized with a platinum point without the patient's experiencing any sensation whatever.

Prevention of Food Adulteration.

A bill for the Prevention of Adulteration of Food has been introduced in the House of Representatives of Pennsylvania.

The bill provides for the establishment of a chemical laboratory in all boroughs and cities having Boards of Health. The laboratory is to be conducted under rules formulated by the State Board of Health, and the borough and city boards are to appoint for the enforcement of the act such chemists, inspectors and clerks as are recommended as necessary by the State Board. It is provided that the boroughs and cities shall pay the expenses. No person is to manufacture or sell, or offer for sale, any article of food or drugs adulterated within the meaning of the act. The penalty is to be a fine or imprisonment or both. The bill does not apply to cases in which any ingredient not injurious to health is added to the food or drug because of the necessity of such addition in preparing articles of commerce, and not fraudulently to increase the bulk, weight or measure, or to conceal inferior quality.

It is also provided that no person, with the intent of selling in the altered state, without notice, shall abstract from an article of food or drug any part of it, so as to affect fraudulently or injuriously its quality, substance or nature; nor shall any article so altered be fraudulently sold. Under the penalty mentioned, no person shall fraudulently sell any compound article of food or drugs not composed of the ingredients demanded by the purchaser. The inspectors are required to inspect all breweries, distilleries, bakeries, factories, dairies, stores and markets where food or medicine is prepared or offered for sale, and secure, by purchase, if necessary, daily, excepting legal holidays, samples of articles likely to be adulterated. These samples shall be submitted to the chemists for examination and analysis. Violations of the act are to be reported by the Health Boards to the proper prosecuting officers. The Health Boards are directed to act in like manner, upon ascertaining that the complaint of any citizen about food or drugs is well founded. All fines and penalties are to go into the respective city and borough treasuries.

Poisoning with Antipyrin.

Dr. Rapin communicates to the *Revue méd. de la Suisse romande*, No. 11, an account of a case of antipyrin poisoning. A young woman 28 years old, suffering with sciatica, had obtained great relief several times from fifteen and one-half grains of antipyrin, without untoward attendant symptoms. The patient was dismissed from medical treatment with the advice to take fifteen and one-half grains of antipyrin immediately if the pain should return. This the patient did five days later. Immediately after taking the drug she was seized with violent burning pain in the epigastrium, vomiting and collapse, bluish-black cyanosis of the lips and cheeks, and an itching exanthem over the whole body. The patient recovered the following day. On the other hand, two patients with arterio-sclerosis died soon after taking the same quantity of antipyrin.

Dr. E. Haffter states in the *Correspondenz-Blatt für Schweizer Aerzte*, No. 23, that he has seen fatal collapse occur in the case of a man 63 years old, suffering with severe pneumonia, one hour after he had received fifteen and one-half grains of antipyrin. The question will be asked whether the symptoms were *post hoc* or *propter hoc*. At all events, however, the steadily increasing reports of threatening symptoms after the use of antipyrin demand greater precaution in its use.—*Wiener med. Presse*, Dec. 16, 1889.

The Inoculability of Leprosy.

Dr. Charles W. Allen, in a letter to the *N. Y. Med. Journal*, Jan. 5, 1889, says that Dr. Berger, of Tampa, Fla., who has made extensive personal investigations of leprosy in Key West, Cuba, and Nassau, as well as in this country, writes to him that he is convinced that there are over a hundred cases of leprosy in Key West alone, and that he has personally inspected thirty advanced cases in that island.

Dr. Augustin A. Crane, who has recently gone to the Hawaiian Islands from New Haven and become a government resident physician in the midst of lepers, wrote Dr. Allen under date of October 29, in which he says: "Father Damien is now dying, having had a rather short course of the disease. He gives as his theory of the contagion that he was performing the last rites in an extremely foul case; that the flies were very annoying during the sacrament, and that he thinks he was inoculated upon an abrasion on the scalp by the flies." Dr. Crane describes the sufferer as being in a horrible condition. He further says: "The convict you speak of is now distinctly leprous. These two points are slight in themselves, but, as far as they go, they seem to throw whatever weight they may have on the side of inoculation as against contagion."

Treatment and Prophylaxis of Cholera.

The Paris correspondent of the *Wiener med. Presse*, Dec. 2, 1888, states that at a recent meeting of the Academy of Sciences, Dr. A. Ivert made a very practical and interesting communication upon the treatment and prophylaxis of cholera. During the expedition to Tonking, Ivert had an opportunity to observe a frightful epidemic of cholera, without being able to influence the disease with remedies. In April, 1887, he assumed the direction of the Nam-Dink hospital, and decided, from the bacillary nature of the disease, to try the effect of corrosive sublimate. He began with small doses, and observed an immediate improvement in the local condition. When the dose was increased, the diarrhœa diminished and the stools became semi-solid. In no case did vomiting occur. This is in such contrast with the symptoms produced by corrosive sublimate in healthy persons, that Ivert assumes that the drug has in cholera a specific action upon the bacilli, or upon the poison developed by them. The result of his experiment was so encouraging that Ivert placed upon this treatment all the patients with cholera who came under his observation from May 1 to June 30. The cases, he says, may be divided into three groups: 1. Pronounced cases of cholera, which present all the classical symptoms of the disease, that is to say, cases in which the disease occurs suddenly, and is announced by vomiting, violent colicky pains, numerous rice water-like evacuations, violent cramps, cyanosis, an algid state, and anuria, to which symptoms asphyxia is sometimes added—cases which tend to death. 2. Cases in which the same symptoms as those noted in the first group are present, but the course is not so rapid—cholera sicca. 3. Cases in the first stage of the disease.

The number of cases treated by Ivert was 45. Of those belonging to the first group, 3 Europeans recovered and one died; and 8 Anamites recovered and 7 died. In the second group, 6 Europeans recovered and 1 died. In the third group, 3 Europeans recovered and none died; 16 Anamites recovered and none died. Total for the three groups, 36 recoveries and 9 deaths.

Ivert employed also symptomatic treatment—hot bottles, injections of ether when there was great adynamia, inunctions of camphor or turpentine for the cramps, tea, coffee, etc.

Prophylactic treatment was instituted in all affections which predispose to cholera. In no instance did a case of cholera develop in the hospital.

As a prophylactic Ivert prescribes:

Liquoris Van Swieten	♏ cl to ccv
Rum	f℥i to f℥i f℥ii
Opii pur.	gtt. xx
Aq. dest.	f℥ii

M. Tablespoonful a day.

Liquor Van Swieten has the following formula:

Hydrarg. bichlor.	gr. xvss
Aq. destill.	f℥xxvi
Alcoholis (80 per cent.)	f℥iii

Treatment of Scrofulous Ophthalmia.

Dr. Augagneur says that the true cause of phlyctenular kerato-conjunctivitis is a rhinitis due to microbes, some of which ascend to the eye through the lachrymal duct. Unless the rhinitis is treated, relapses are incessant. He advises insufflation into the nasal fossæ of the following powder:

Powdered camphor,
Boric acid,
Sub-nitrate of bismuth, equal parts.

He thinks the microbes are conveyed to the nostrils upon the fingers.—*Gazette Hebdomadaire*, Dec. 21, 1888.

NEWS.

—A sanitary expert has been engaged to make an examination of the sewage system of Jacksonville, Fla.

—Those who intend to go abroad will be interested in learning that small-pox is reported to be prevalent throughout Italy.

—It is reported that Dr. R. S. Huidekoper intends to resign from the Veterinary Department of the University of Pennsylvania.

—Dr. B. L. Batterbury, in a communication to the *British Med. Journal*, Oct. 27, 1888, recommends coffee as a vehicle for antipyrin.

—The Governor of Indiana advocated, in his inaugural address, a local option law, and recommended severe penalties against adulteration of food.

—Dr. J. D. Mercur, of Philadelphia, was recently so fortunate as to capture a burglar just after he had broken open the front door and was going upstairs.

—In a communication to the *Medical Age*, Jan. 10, Dr. F. T. Paine reiterates his previous assertions as to the anaphrodisiac properties of salix nigra.

—The daily papers state that a colored boy three years old is exciting much interest in New York City through his exhibition of marvelous feats of memory.

—Dr. F. A. Neely has retired from the editorial staff of the *Memphis Medical Monthly*, because the work interferes with his practice and his teaching.

—Dr. Tanner has proposed a fasting contest in which he is to drink only water, while the other participants are to have all the alcoholic beverages they desire.

—A sophomore in Cornell University has developed small-pox. An order has been issued by the President of the college requiring every student to be vaccinated.

—The *N. Y. Med. Abstract*, Nov., 1888, says that M. Gariel, a professor in the Nantes Medical School, proposes a combination of two important therapeutic measures in his method of "general hydropathic electrization." This consists simply of a shower bath to which wires are attached in such a way as to pass electric currents through the water at the time of using it. Patients who have been unable to take the ordinary cold douche appear to have used this modification of it with advantage, on account of the quick reaction which follows its employment.

HUMOR.

MOTHER—I want to get a real sweet, smooth name for my baby daughter.

Gouty Uncle (who is thinking of a salad) —Well, why don't you call her Olive Oil? —*Boston Gazette.*

DOUBTFUL COMPLIMENT. —Hostess—"I hope you are enjoying your dinner, Mr. Fowler." Guest—"Yes, indeed. This country air has given me such an appetite that I can eat most anything."—*Boston Beacon.*

AT THE CONCERT.—"Why are these boys called 'child wonders'?" "First because they are so dexterous with their fingers; second, because they continue to be twelve years old for four or five years." —*Fliegende Blätter.*

TRUTH FROM TRUTHFUL JAMES.—"Do you swear to your circulation?" asked the advertising agent of the truthful country editor.

"No," said the truthful country editor, truthfully, "I swear at it."—*Somerville Journal.*

THE ONLY SAFE PLAN.—Oculist—"When did your eye first become inflamed?"

Patient—"Yesterday. I went up to a lady to speak to her and the peak of her bonnet—"

"I see. We have many such cases. Use this lotion and be careful while the present fashion lasts to do your talking to ladies by telephone."—*Record.*

MRS. DOLLIVER—"Oh, Henry, I have dropped the water pitcher out of the window, and I saw it light on an elderly man." Mr. Dolliver (turning pale)—"Great Scott, Jane! You don't know what damage you may have caused!" Mrs. Dolliver (in tears) —"Yes I do. It's pure china and can't be replaced for less than $20. Oh, what shall I do?"—*Harper's Drawer.*

TOO GOOD FOR LIFE.—Little Edith was required by her mother to assist in the household labor, and it fell to her lot to dust the stairs. When dusting day came around, Edith would moan "Oh, how unhappy I am!" but after she had completed her task, she would change her tune and say "How happy I am!" On the last recurrence of the dreaded day, Edith went about her work without being told. When she had finished, however, she came into the sitting-room with a sad, troubled face. "Mamma," she said, "I'se 'fraid I'se going to die. I've got so good that I love to dust."—*Boston Transcript.*

EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO:,
PHILADELPHIA.

IF

You have never prescribed Lactated Food, why not do so NOW? A scientific preparation, its formula recommends it to every physician.

Anyway, let us send you our complimentary portfolio of baby pictures—they are beauties. Sample of Lactated Food mailed to any physician unacquainted with its merits.

WELLS & RICHARDSON CO., Proprietors

BURLINGTON, VT.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

CLINICAL LECTURE.[1]

A CASE OF SYPHILITIC INFECTION COMPLICATED BY EPILEPTIFORM CONVULSIONS, KERATITIS, ETC.

BY HENRY M. LYMAN, M D.,
CHICAGO, ILL.
PROFESSOR OF PHYSIOLOGY AND DISEASES OF THE NERVOUS SYSTEM, RUSH MEDICAL COLLEGE; PROFESSOR OF THEORY AND PRACTICE OF MEDICINE, WOMAN'S MEDICAL COLLEGE.

(Reported by William Whitford.)

Gentlemen: Here is an interesting case. It is an illustration of the ravages of syphilis. The mother of the patient was infected by her husband, and the first child that was born was also a victim of the disease. This is the second child. The mother has had five miscarriages, and now after that experience the child born since the last miscarriage is healthy—an example of the subsidence of the disease. The second child shows well-marked evidences of infection; and the most prominent symptoms are connected with the eye.

In addition to the symptoms and changes which you observe in the eyes, there have been pain and headache, and at one time the child suffered from pain in the legs, a periosteal inflammation involving the tibia. But the most remarkable thing, and what brings her here, is the fact that about a year ago she began to have convulsions. The child would be taken several times during the day with a fit; she would then run to her mother for shelter, as children are apt to do, and would remain on her lap until the paroxysm was over. After a few minutes the child gradually recovered consciousness. She had eight or ten of these paroxysms during the day. Under treatment they have become less frequent and less severe, until now, after the expiration of one year, she does not have completely developed convulsions.

This case is interesting as showing how

[1] Delivered at Rush Medical College, October 25, 1888.

convulsions may occur as a consequence of disease of the brain, which resembles epilepsy, and yet is not to be considered as true epilepsy. We employ for such cases the term "epileptiform convulsions." Eclampsia is a name that is sometimes used, but the word epileptiform is a good one, because it indicates the resemblance between the phenomena that occur in these cases and the phenomena of epilepsy. True epilepsy is a disease of the brain, which perhaps is as extensive as the brain itself, and is generally incurable. It is characterized by recurrent convulsions, which are repeated, in spite of treatment.

Professor Lyman then introduced to the class Dr. Alfred Hinde, ophthalmologist to the clinic, to explain the condition of the eye. Dr. Hinde spoke as follows:

The affection of the eye in this patient is the one so frequently present in children affected with hereditary syphilis. It shows itself usually after the fourth year, being preceded by a period of latency of the constitutional affection. The affection referred to is known as diffuse parenchymatous, or interstitial keratitis, and is seen most frequently in children and young adults. It usually affects both eyes, though it may be in varying degree. It appears first as a slight opacity covering the surface of the cornea; later the process extends more deeply, and varies in its increasing density in different portions of the same cornea, until the vision of the patient may be greatly reduced, owing to the entire thickness of the cornea becoming opaque.

There is, however, another disease of the eye so frequently present in syphilitic subjects that we must be ever on the alert for it. It often coexists with keratitis, and is known by the name of iritis. Now, on carefully examining the right eye of the patient, and selecting the most transparent portion of the cornea, the iris may be seen to be swollen, muddy-looking, and its pupillary margin irregularly thickened and attached to the anterior capsule of the lens—the latter condition being known as a posterior synechia. Hence we must call the condition present in the right eye kerato-iritis. As the rosy zone of the sub-conjunctival vessels is absent, and there is also a lack of vascularization of the cornea itself, the stage of the disease is subacute or chronic.

Jonathan Hutchinson, of London, many years ago observed that, coexisting with this disease, there is also frequently present in the young subjects of hereditary syphilis a peculiar coloring and conformation of the teeth, more especially of the two upper permanent central incisors. The peculiarity consists in a dirty brownish coloration, together with a dwarfing, or narrowing and shortening of these teeth, with a gouged-out condition of the central portion of the cutting end, so that a pegged appearance of the two teeth results. At one time he thought that, in a well-marked case, such teeth alone were sufficient to prove the patient to be syphilitic. The observation was a praiseworthy one, but the conclusion is too sweeping. In many cases there would seem to be a strange coincidence to say the least, of the three conditions—syphilis, diffuse parenchymatous keratitis, and Hutchinson's teeth. Yet in our little patient the pegged teeth are not present. About the seventh year the permanent incisors appear, but this child is in her eleventh year, and the upper central incisors are not yet fully grown. Their color is white, the teeth are broad, and their cutting edges are serrated instead of pegged—none of which conditions is characteristic of Hutchinson's teeth; and yet we have a positive history of hereditary syphilis.

The late appearance of the teeth may be attributed to general malnutrition, and the latter is certainly due to the specific disease.

The treatment for the eye is the same as that for the general condition; the time required for cure will necessarily be long; the result will largely depend upon the character of the pathological changes in the corneæ and uveal tracts of the two eyes. The fibrinous exudate and cellular proliferation will be largely absorbed under appropriate and long-continued treatment. The new connective tissue formation in the corneal layers will, however, remain. Where the iris, ciliary body, and choroid have been involved, these parts will be only partly repaired.

Again, the retina has probably not escaped injury. Unlike other forms of keratitis this variety shows little tendency to ulceration and abscess, hence irritants, judiciously used, are admissible in its local treatment. Therefore, to aid the absorption of the opacity of the cornea a mild vascularization of the latter must be produced and kept up. This condition may be brought about by warm fomentations, frequently repeated, and long-continued; and, as soon as the corneæ begin to clear up, by daily insufflations of pure calomel, or by the daily use of an ointment of the yellow oxide of mercury, together with massage of the eyes. Too much irritation

must be avoided, as well as too little, otherwise an increased exudation will result on the one hand, or, on the other, a stationary condition of the eyes will continue. Each case must be treated on its own merits, and strictly routine directions, suitable for all cases, cannot be given.

Again, in those patients in whom the uveal tract is involved, instillations of solutions of atropine are resorted to, and the effect of irritants and astringents must be most carefully watched, lest the iritis be aggravated and an extension of the inflammation to the choroid be brought about. If the latter accident happen, an irido-choroiditis results, which would cause a shrinking and atrophy of the eyeball and result in blindness.

Improvement in nutrition and good hygiene are the main indications in the treatment of these cases. Easily digestible and nutritious food, together with cod liver oil and syrup of the iodide of iron, are the agents most suitable for their cure. Where the greatest improvement in nutrition has been attained, and where evidences of struma are absent, minute doses of the bichloride, long continued, will be found to be beneficial, especially so if combined with the tincture of the chloride of iron.

Professor Lyman, continuing, said: The interesting thing to consider in this connection is the relation between the disease and the convulsions. How does it happen that the patient has been having convulsions—convulsions that did not appear until a year ago? Why did they not occur during the early years of life when the nervous system was exceedingly sensitive? How does it happen that the patient passed through the early period of life without convulsions, but developed them at the age of ten years? I think it is due to peripheral irritation. Where is it situated? At the periphery of the brain. The convulsive centers, as we may call them, are located at the base of the brain; they are connected with the pons, the medulla oblongata, with the anterior and lateral columns of the cord, and with the gray matter in the cord. These, then, are the structures principally concerned in the matter of convulsions. It is due to irritation of these centers at the base of the brain that convulsions are usually produced. In many cases of true epilepsy we can trace the connection between the irritation at the surface of the brain and the convulsion that originates apparently in the convulsive centers at the base of the brain.

A patient has, for example, an injury or a blow upon the head, partial fracture of the bone, a depression of the internal table; subsequent inflammation takes place. There is a localized inflammation of the meninges of the brain. This produces local irritation of the surface of the brain, and, as you will remember, the lateral portion of the cortex of the brain is excitable. Irritation of an electrical character applied to the surface of the lateral portion of the brain adjacent to the fissure of Rolando will produce movements in the muscles that are connected with the spinal cord below. In the event of a disease, or an inflammation produced by an injury in that region, the irritation of the meninges will be communicated in many instances to the cortical structures adjacent to the fissure of Rolando, and may be propagated downward over the fibres that connect these parts with the ganglia at the base of the brain and in the spinal cord. If these irritations are sufficient in intensity, convulsions will occur. This form of epilepsy is known as traumatic.

Now, syphilis is a disease which very frequently produces inflammations of the covering of the bones of the body, the periosteum. This patient complained of pain in the leg at one time, a pain that was referable to the bone undoubtedly; it was an inflammation of the periosteum covering the tibia. Similar inflammations attack the bones of the skull, that is, an inflammation of the periosteum lining the cavity of the cranium may take place. This inflammation will run its usual course. It reaches its height, then subsides, disappears, and the patient may recover. This is true of certain cases. In others the severity of the disease is so great that the bones may become ulcerated, excavated, honeycombed here and there by the processes of intense inflammation, destroying the bone, and producing necrosis of its substance. It may go so far as to cause an exfoliation of the bone itself, the dead portions separating from the cranium just as they would be separated from the tibia or from any other part in which necrosis takes place. There is no limit to the ravages which may be produced by the syphilitic process; when it attacks the structures of the cranium the process is not always so severe as that which I have mentioned; but a syphilitic inflammatory condition involving the internal lining of the cranium, producing what is called pachymeningitis, would encroach inevitably upon the thinner membranes of the brain, the pia mater and the arachnoid,

and produce an inflammatory action which might excite the adjacent cortical structures. It is in this way that we may explain the occurrence of convulsions in certain cases of syphilitic disease of the cranial structures.

An additional support to this view is derived from the effects of treatment. The child, as soon as the disease was recognized, was placed upon anti-syphilitic treatment, which produced an amelioration of the symptoms. The convulsions are not now so frequent as they were formerly. Probably they will disappear as the exciting cause vanishes under the influence of treatment.

The affection in the present instance, then, is different from what is called idiopathic epilepsy, in which the disease comes on as a consequence of interstitial changes in the substance of the brain itself. It is a difficult thing to manage: it is almost uncontrollable with medicines. But where we have mere peripheral irritation, the removal of the irritant is the principal thing needed.

This is an admirable case in which to prescribe mixed treatment. The remark made by Dr. Hinde in the matter of treatment is an important one for you to remember. He says he would recommend the administration of syrup of iodide of iron and cod liver oil, and that is a matter of great importance in the treatment of not only this case, but the majority of cases of epilepsy. Patients of this kind—you may say all epileptic patients—are suffering from a deterioration of the nervous system. There is, even in cases which appear to be quite healthy, less than the normal quality of resistance and nervous energy, so that while you administer medicines which are intended to control the convulsions, such as bromide of potassium, and medicines for the treatment of the syphilis, such as mercury, it is necessary also to administer remedies which build up the nervous system.

It was frequently remarked by Dr. Willard Parker, of New York, that mercury in a case of syphilis should not be given until the patient was ready for it. In the treatment of such cases we often have to treat an anæmic, exhausted patient. The anæmia may be due to insufficient food, bad air, unfavorable surroundings, etc.; but the effort should first be made to remove the anæmia, for if this cannot be done, there will be failure to secure the desired benefit from the specific treatment. It is sometimes desirable then, as Dr. Parker has said, to forget the fact that the patient has syphilis or epilepsy and address treatment to the condition of general cachexia, endeavoring to stimulate the function of the blood-making organs. It is important to determine if there is actual deficiency of hemoglobin in the blood. This fact can be ascertained in a few minutes, as I showed you the other day. If it is absent, administer iron to the patient. Here the syrup of iodide of iron becomes useful; it is beneficial in a large proportion of these cases. Give your patient iron and good food; let him secure an abundance of pure air; then presently, when the general condition improves, it will be proper to administer the specific drugs that are required for the perfect cure of the patient.

The treatment of epilepsy also requires much attention in the matter of diet. If we neglect the diet of the patient we shall fail to get good results, because the character of the diet determines in a great measure the proclivities of the individual. It is desirable to reduce the excitability of the nervous system, to get the patient into a condition as much as possible like that of the slow moving, torpid class of animals.

If a patient manifests a convulsive tendency, endeavor to get him into the slow, tranquil, quiescent condition of a herbivorous animal; the only way to do this is through attention to the matter of diet. Patients afflicted with epilepsy are subject to nervous excitability, neuralgia, headache, and various nervous disturbances. Eating of meat, then, should be forbidden in such cases; the patient should be fed with fruits, bread, vegetables, and substances which tend to limit the consumption of albuminous matter; thus the whole character of the patient will become modified in a favorable way. Evidence of this fact is seen in the case of children who are not really sickly, but who are brought up on a meat diet. They are excitable, passionate, quarrelsome, ill-tempered, and hard to get along with; whereas, if they are put on a vegetable diet for a number of months, they will become more tractable and far easier to manage. The same holds true with regard to the different races of the world. Where there is a great deal of meat consumed by any race, that same quarrelsome, active, vigorous, energetic character is manifested.

In the treatment of these cases, forbid animal food; keep the patients on a vegetable diet, and the severity of the nervous disorder will be considerably diminished. This, then, is a point well worthy of consideration when taken in connection with the diet that Dr. Hinde has already recom-

mended. Cod liver oil, which he has advised, is an article of diet not to be considered objectionable, though it is derived from an animal. In its effects it is bland and un-irritating. It does not introduce into the nervous system those chemical elements which give the nervous system its excitable character. Therefore, cod liver oil is one of the best remedial agents, both as medicine and as food, that you can administer to patients of this description.

Another reason for the old maxim in the treatment of epilepsy holds good, I think, in this connection. It was Hippocrates, who said that patients afflicted with epilepsy should dig in the dirt and live as much as possible near the soil. Now, the reason for that is to be found in the fact that people who live out of doors, and who use their muscles in digging, work off a great deal of surplus energy in that way; and, furthermore, by laboring out of doors, occupying themselves with agricultural pursuits, they are placed under favorable circumstances, other things being equal, for healthful nutrition. Of course, this would not hold good in a malarious climate, or in a place where there were other unfavorable environments. But, as a general rule, the conditions of the agricultural laborer are far more favorable to health in epilepsy than are those of the mechanic in a large city. The mechanic lives in an unwholesome atmosphere during a large portion of the time; his brain is over-taxed in many instances; his associations and surroundings are connected with more or less excitement and turmoil. On the contrary, the agricultural laborer does not over-tax his intellectual faculties; his appetite improves; his digestion is confirmed, and his whole life tends to the production of a tranquil state of the nervous system, which is a great aid toward the prevention of a recurrence of epileptic paroxysms.

—As an instance of how small-pox may be spread, the following story taken from the *Lancet*, Jan. 5, 1889, is not without interest. A supper was held in a certain public-house at Ormsby, near Middlesborough, England, and, in order to provide sufficient accommodation in a long room, a partition was taken down, and what had served as a bed-chamber was added. In this chamber a servant girl had been recently lying ill with small-pox. A few days after the supper, no less than nine cases of small-pox, believed to have originated in this place, occurred.

COMMUNICATIONS.

INCOMPLETE SPONTANEOUS VERSION AFTER A HAND WAS EXTRUDED FROM THE VULVA.

BY C. S. SHEPARD, M.D.,
LA PORTE CITY, IOWA.

On August 21, 1888, Mrs. S., a German woman, 38 years old, of medium build and pelvic capacity, gave birth to twins. She was already the mother of five healthy children. When first seen her labor was well under way, the os dilated to the size of a silver half-dollar, and the membranes intact. A normal vertex presentation was made out. The pains were feeble and irregular, making labor extremely slow. The product of conception had made the abdominal tumor of unusual size, and consisted, as I suspected and predicted, of twins, together with a large volume of amniotic fluid.

The parturient canal seeming to be of ample dimensions, the patient was given ten grains of quinine and fifteen drops of fluid extract of ergot. The effect of the medicines was marked in a short time. The futile, capricious pains became converted into efficient expulsive contractions, which soon caused the extrusion of a fine girl weighing six and a half pounds. The interval of rest that usually occurs between plural births was wanting in this case; for, before the cord could be treated, extremely severe uterine contractions came on, accompanied by a gush of fluid. Upon examining for the presenting part, a hand and forearm were found occupying the vagina. The pains were now expulsive, vigorous, and recurrent at short intervals. In a very few moments the hand and forearm emerged from the vulva, and the shoulder began to press closely the pelvic brim. The position was dorso-anterior, the head lying in the right iliac fossa; hence the left shoulder presented.

In the brief intervals between the contractions I passed my hand into the uterus, grasped and tried to bring down a foot. The waters had nearly or quite all escaped. I was unable to make the desired version, whether because the womb too closely grasped the child or from lack of skill on my part, I do not know. It may be that both were factors in the case, but, after persevering in the effort to what seemed the verge of temerity, I withdrew my hand,

leaving matters, as the lawyers would say, *in statu quo*.

The husband was taken aside and informed of the serious aspect of the case and that an operative measure might be required to terminate the labor with safety to the mother. On returning to the patient, having been absent perhaps fifteen minutes, I found her having exceedingly severe pains, and a careful examination disclosed the fact that the prolapsed hand was slowly receding into the uterus, while the shoulder was beyond reach. The head and upper part of the trunk now ascended steadily toward the fundus of the uterus, and the side, back, and finally the breech, of the child presented at the mouth of the womb. The child was born a few minutes later, dead. The cord failed to pulsate, the mouth and lungs contained fluid. The passage of the head through the pelvis was too expeditious, it seems to me, to have resulted fatally. The placenta was single and was readily removed. The mother had no untoward symptoms and the first-born child was hearty and vigorous. The still-born child weighed seven pounds, and was perfectly formed. The mother plainly felt the movements of this child for a short time after the first was born. Both children were females.

Lusk defines spontaneous version as "the process by which either a transverse presentation is transformed through Nature's unaided efforts into a longitudinal one"—or by which a normal position is either partially or completely reversed. This form of version, though often occurring during pregnancy, is seldom met with as a feature of labor. Playfair speaks of it as one of the "possible terminations" of shoulder presentations, and strongly urges that such termination cannot be relied on in practice. Lusk says: "According to the statistics of Housemann, cases of spontaneous version after rupture of the membranes are nearly five times as frequent as those occurring before their rupture. The same author states that the head presented in eighty per cent. of the cases occurring before rupture of the membranes, and the breech in seventy-five per cent. of those taking place after the occurrence of that event." He also states that: "An undilated cervix, powerful contractions of the uterine fibers, and a fully developed child are essential conditions for the occurrence of spontaneous version after rupture of the membranes."

In the case in hand two of these conditions obtained—the powerful contractions and the fully developed child; for, though one of twins, the size of the child was nearly equal to the average size of children singly born. But the other condition—the undilated cervix—was lacking. A number of cases recorded by different observers show that a widely distended os does not necessarily preclude spontaneous version. Playfair says: "A few authenticated cases are recorded in which the same fortunate issue (*i. e.*, spontaneous version) took place after the shoulder had been engaged in the pelvic brim for a considerable time, or even after prolapse of the arm, but its probability is necessarily much lessened under such circumstances." Playfair further states that: "The mechanism of spontaneous version, or the favoring circumstances, are not sufficiently understood to justify any positive statement with regard to it."

Lusk, however, explains the mechanism thus, holding, as will be seen, an undilated os as an essential condition: "The os is only partially dilated. The pains force the presenting part into close contact with the os internum. Owing to the absence of an equally distending bag of waters, the os does not dilate, and soon assumes a condition of tetanic spasm, during which it can be felt as an unyielding, cartilaginous ring. The contractions of the fundus of the uterus having now become more forcible, the fetal head or breech, as the case may be, is subjected to violent pressure. Inasmuch, however, as the unyielding os prevents any progress downward, the presenting part is displaced laterally, and that part of the fœtus which previously occupied the fundus is forced into the pelvic entrance." "Cazeaux believed that it is produced by partial or irregular contractions of the uterus, one side contracting energetically, while the other remains inert, or only contracts to a slight degree. To illustrate how this may effect spontaneous version, let us suppose that the child is lying with the head in the left iliac fossa. Then if the left side of the uterus should contract more forcibly than the right, it would clearly tend to push the head and shoulder to the right side, until the head came to present instead of the shoulder.

"A very interesting case is related by Geneuil, in which he was present during spontaneous version, in the course of which the breech was substituted for the left shoulder more than four hours after the rupture of the membranes. In this case the uterus was so tightly contracted that version was impossible. He observed the side of the uterus opposite the head con-

tracting energetically, the other remaining flaccid, and eventually the case ended without assistance, the breech presenting. The natural moulding action of the uterus, and the greater tendency of the long axis of the child to lie in that of the uterus, no doubt assist the transformation, and much must depend on the mobility of the fœtus in any individual case."

AMPUTATIONS OF THIGH AND LEG.[1]

BY MORDECAI PRICE, M.D.,
PHILADELPHIA.

The subject I wish to bring before the Society to-night is one of deep interest—to me at least, and to all others who are alike unfortunate in having lost a limb. In performing amputation on the leg, the chief object of the surgeon of the day seems to be to remove the limb and save life—the future comfort and usefulness of the patient being minor considerations. The comfort and usefulness of patients who are subjected to amputation of the leg have received my personal attention through the entire period of my professional life. This has been my latest thought at night, my first consideration in the morning; and I have been painfully reminded many times during the day of the importance of changes in the present surgical practice. I see no reason why in this department we should narrow our surgery to a strict following of the *dictum* of a school of surgeons a century old: why we should not, in step with other departments of surgery and medicine, adopt those new truths which our advanced art and science and wider experience approve.

I ask your critical consideration of the few changes I propose to suggest. As a student I often marveled at the numerous amputations done near the ankle and through the knee, for the reason then given: to save all the limb possible, apparently without due consideration of the discomfort and suffering to follow, and of the usefulness of the limb. I have waited for years hoping that some of our eminent surgeons, members of this Society, would bring the subject before us, when I expected to be able to say something upon the subject. Like many other departments of medicine and surgery, however, this seems to have been looked upon as one of the subjects forever settled. For as far back as the works of surgery of the 18th century I find the same old plates, the same old positions for removal of the limb—where it is a matter of selection with the surgeon—as I find in use to-day. Sometimes the accident comes to the patient's rescue and removes sufficient of the limb to compel the surgeon to give the patient a good stump. In an amputation to-day in the foremost hospital of the world—the Pennsylvania—if the location of the injury left a choice as to where the limb should be removed, it would be done through the ankle or at the lower third of the leg. I suppose you ask "Why not?" I would answer that question by asking: Why do we amputate at all? The answer would be: first, to save life; and, second, to make a useful limb. Now, we can save life as easily by one method as by the other. Why not then operate solely for the best interest of the patient? In an amputation of the leg all that is left below the middle of the middle third of the leg is useless and in the way, and gives that much more room for ulceration and friction-sores. Let me tell you, gentlemen, these are weighty considerations in an amputation, for they compel the wearer of an artificial limb either to endure great suffering or to leave the artificial limb off, as I can abundantly testify from personal experience. Nearly three-quarters of a century ago, Gibson used the following language: "As much as possible of the thigh should in all cases be saved. But the rule does not always hold good in amputations of the leg. If, for example, the leg be amputated just above the ankle, the bone, from the deficiency of surrounding muscle, cannot be well covered and is therefore not calculated to bear the pressure of an artificial leg. On this account the patient is obliged to have an instrument of the kind adapted to the knee, and the leg therefore is carried out behind at right angles with the thigh and by its weight greatly incommodes the patient, so much so, indeed, that I have known two or three to submit to a second operation, for no other reason than to get rid of the incumbrance." This Dr. Gibson gives as his professional experience. I personally know of a number of reamputations for no other reason than the suffering, discomfort, or absolute impossibility of wearing an artificial limb upon a long stump. After the application of an artificial limb there is a constant diminution of the size of the stump. Its nutrition being continually interfered with, and the parts being of low vitality, consequently, when we have ulceration or friction-sores, or injuries of any

[1] Read before the Philadelphia County Medical Society, Jan. 23, 1889.

kind, it is with great difficulty that they are induced to heal.

There is another element to be taken into consideration. As soon as the artificial limb is left off, and the patient assumes an upright position, the stump is greatly enlarged by a species of œdema which takes place almost immediately, leaving the parts in no condition to heal. The stump has the feeling of being cold and almost lifeless, and if exposed to cold it would be the first to freeze. It is almost impossible to keep it warm, when the artificial limb is left off.

Amputations through the knee joint give in many cases a very bad surface to bear the weight of the body, and a leg is rarely worn with comfort. Such an amputation absolutely prevents the application of a limb of full length, as the knee joint would have to be lowered some three inches for want of room, making at best a useless appliance. Amputate therefore—if it is a matter of selection—through the lower third of the thigh. An amputation below the middle of the leg is objectionable on account of the length of the stump, which presents occasion for ulceration and is difficult to dress properly so that the limb may be worn with comfort. Every inch of stump over five or six inches below the knee involves that many hundreds of hours of suffering and distress to the patient. The additional chance of life does not add one feather's weight in favor of the long amputation. Amputation at the lower third does not give sufficient room for a strong ankle joint, and therefore adds greatly to the wear and tear of the limb, thus adding largely to the expense. Amputations through the ankle may give the patient something to walk on, but this is oftentimes accompanied with great pain. It often gives him a poor excuse for a limb, and completely prevents any mechanical appliance from aiding him in the least, and forever prevents him from hiding his terrible deformity. If ever there was an appliance to which the term "slip-shod" could be appropriately applied, it is to those intended to imitate nature in these cases. The usefulness of an artificial limb is in proportion to the simplicity and completeness of its mechanical construction. The nearer it resembles the human limb in all its parts, the more perfectly it fills its office. There is one fact associated with these cases to which but few of you, perhaps, have given a thought; that is, the ever present and painful consciousness of physical deformity which the patient has, and the fact that his maimed condition closes to him many avenues of honorable, useful and lucrative employment. This applies especially to the case of civilians; to the soldier it is different; to him the loss of part of a limb is unchallenged testimony of gallant and heroic sacrifice.

ANTISEPSIS AND THE COUNTRY PHYSICIAN.

BY G. WALTER BARR, M.D.,
BRIDGEPORT, ILL.

The warning by Dr. J. M. Taylor, in the REPORTER of December 8, 1888, regarding antiseptics incites me to contribute briefly my experience on the same subject. I practise in the country, over the worst roads in the nation, and when I leave home have no idea whether I will have a case of placenta prævia, fractured femur, typhoid fever, or hypermetropic headache before I return. Under such circumstances the practitioner must be physician, surgeon and inventor combined. Our city cousins have no idea of our trials and emergencies, but I verily believe that the situation has advantages, as a discipline, over the conveniences of town practice. With experience as a student in several medical colleges, the best training I ever received was the teaching of Professors Gross and Brinton at the Jefferson College, where we saw little intricate mechanism or perfected instruments, but heard much about improvised helps and "trunkmaker's board."

Having used the best possible judgment in discriminating between new remedies and fads, the country practitioner is liable to be shy of furors like Bergeon's treatment, but to take up and hold fast that which is good. The greatest God-send we have received for many a day is antisepsis. No one has a more correct idea of the word than the country doctor. He cannot carry the apparatus of a hospital and must somehow create the condition extemporaneously with all kinds of means. Consequently he can not follow a formula, but must know exactly the end to be obtained and the principles to be followed in attaining it. The most convenient antiseptic for our class is bichloride of mercury, because of its very small bulk in ratio to its efficacy. Ammonium chloride is always carried for cough-mixtures, and this dissolves the bichloride in rainwater. Enough gauze for one dressing has a small bulk, and so has a suitable quantity of iodoform. With these

in his case, the country doctor takes whatever is at hand and operates antiseptically. When he insists on having a dish instead of a tin cup for his solution, his learning is wondered at; when he amputates some fingers and tells the patient not to touch the dressings until he returns in a week or so, the old nurses think he is daft; and when he takes off the dressings and shows a healed scar he is regarded as either an angel or a wizard. But aside from the carnal benefits to his purse, antisepsis saves him a world of trouble. I dress an operation-wound antiseptically and tell the nurse to notify me in case the secretions wet through the bandage, or any fever or unpleasant odor is noticed. Then I return when I am next in the neighborhood to remove the dressings. This is somewhat better than riding half the night in the rain. Of course some cases cannot be so treated; but still antisepsis is a great boon. I will not discuss the question of the value of antisepsis *per se*. The country doctors have waited until the matter is past the experimental stage; if they will learn the fundamental principles of the art and use it after their usual customs, they will never discard it.

A PIN IN THE BLADDER.

BY HONORA A. ROBBINS, M.D.,
BLOOMSBURG, PA.

The following case has some points which I have no doubt will prove of interest to the readers of the REPORTER.

A single woman, thirty-nine years old, first came under my care in October, 1887, for chronic metritis. Two months afterward, the following May, I was called to see her, and found her suffering with acute cystitis. For six days there was retention of urine. Several times during the introduction of the catheter, she exclaimed, "There is something sticking me."

At the patient's request, an examination was made, and the point of a pin was felt penetrating the anterior wall of the vagina, and, with some difficulty, an old-fashioned ordinary toilet-pin, an inch and a quarter in length, bent at an obtuse angle, covered with rust, was extracted.

The woman said she had swallowed two pins in 1864. She was in the habit of having pins in her mouth, and, while reading, she thoughtlessly swallowed two. One passed directly into the œsophagus, and the other pin could be felt, by a physician, in the pharynx. During his efforts to extract it, it too passed into the œsophagus.

For seventeen years she was subject to spasms. During the last seven years she has suffered with severe attacks of intestinal colic.

Two years ago a straight tarnished pin was removed from the rectum. It lay transversely just within the sphincter ani.

After I had removed the pin described above, the symptoms of acute cystitis at once subsided, and the woman made a rapid recovery.

PERISCOPE.

Hysterical Traumatic Arthralgia.

M. Charcot (*Progrès Médical*, January 28, 1888) again draws attention to a form of joint affection which may have a traumatism for its origin, but yet rest on a purely neurotic basis. A case of this kind formed the subject of a clinical lecture recently delivered by him. The patient, a young girl, had fallen on her left knee seven months before. Since that time the knee had been swollen, and the patient had kept to her bed. A cursory examination would leave the impression that the patient was the subject of a grave joint affection. The joint was considerably swollen, and its outlines were gone. Movement and manipulations caused considerable pain. The skin over the joint was red and shiny, the local temperature was somewhat higher than that of the opposite side. The limb was in a position of semiflexion, and the muscles were markedly atrophied. Analyzing the case, it was found, however, that there had been no fever, and there was no emaciation such as would attend a serious disease of the joint. The redness of the skin was due to all kinds of topical agents that had been employed by various physicians whom the patient had consulted. On further examination, it was found that the patient had left hemianæsthesia and ovarian pain on the left side. There was anæsthesia of the pharynx, and there was considerable diminution of the field of vision of the left eye. There was hyperæsthesia over the third, fourth, fifth, and sixth dorsal vertebræ. Under chloroform it was found that the joint was quite movable and that there was no crepitation to be felt.

The treatment of these cases must be chiefly moral. Hypnotism and suggestion may be tried. The various means employed in hysteria are here called into requisition. —*N. Y. Med. Journal*, Jan. 19, 1889.

Mode of Action of Antipyrin in Typhoid Fever.

Dr. N. S. Davis, Jr., in a paper read before the Chicago Medical Society, and published in the *Med. Record*, Jan. 19, 1889, says that he concludes from his own study of the action of antipyrin in typhoid fever, that it is certainly not a specific for the disease, and that it is of little or no use because of the antipyresis which it produces, and is of very limited use because of any of its other modes of action. It certainly, he says, cannot replace hydropathic treatment, with which it is so often contrasted. It must be remembered, however, that the chief benefit of the latter is not in its antipyretic effect, but in its stimulating influence upon the nervous system, upon nutrition, upon the circulation, and often upon the excretion of urine.

Suggestion of a New Use for Nitro-Glycerine.

Dr. W. C. Kloman writes to the *Maryland Med. Journal*, Dec. 15, that he has recently had occasion to prescribe nitro-glycerine and to observe its physiological action. He has come to the conclusion that the statement that it abolishes the inhibitory function of the pneumogastric nerve is correct; at the same time he observed that the capillaries, and possibly also the smaller arteries, were conveying far more blood than they had done before its administration. This was evidenced by the flushing of the face and the increased warmth of the extremities, while the radial pulse beat fuller, freer and more rapidly.

Dr. Kloman ordered the drug in a case of cardiac asthma, in a man 82 years old. There was no evidence of cardiac disease *per se*, but simply a weakness of the heart's action, with a want of coördination of the action of the right and left side of the heart, due to senile degeneration. Strophanthus had been given, but it failed to be prompt enough to avert the attacks of asthma.

He was obliged to give three drops of a one per cent. solution of nitro-glycerine to obtain any sensible effect in this case. On Nov. 29, 1888, Thanksgiving day, the patient spent the afternoon and evening away from home, and returned thoroughly chilled, feeling also the commencing shortness of breath. His wife administered to him a three-drop dose of the solution of nitro-glycerine, and the patient assured Dr. Kloman the next morning that the effect was almost instantaneous: he soon became warm and was relieved.

Dr. Kloman concludes as follows: "Now, reasoning from its physiological and its therapeutic action in this case, it seems to me that it would act highly beneficially in cases of threatened gangrene of the extremities. So far as I know, this idea is original with me, and I should be glad to hear of the results of a trial in a case of this kind."

Beta-Naphthol in Typhoid Fever.

J. Mitchell Bruce communicates a paper on β-naphthol in enteric fever, to the *Practitioner*, December, 1888. He gave the naphthol suspended in milk, and a small quantity of pure milk was taken after the dose. It must be given frequently, he says, in order to keep up a constant effect, and small doses have also the advantage of not causing the pungent after-taste in the throat which is liable to be produced. To adults it may be administered in gelatin capsules, or by the following formula, which seems the most satisfactory after several trials:

β-naphthol	gr. xx
Tr. aurantii	f ℥ ii
Syr. limonis	f ℥ ss
Mucil. tragacanth	f ℥ iii
Aquam	ad f ℥ vi

M. Sig. Dose, one ounce.

In four cases, two of which were in boys 12 years old, the naphthol was taken in doses of three and a quarter grains every two hours during the whole course of the disease, until the temperature remained normal for five or six days.

The number of cases would seem to be too few to furnish trustworthy conclusions. Nevertheless, Mr. Bruce concludes:

"1. That the production of intestinal antisepsis is a rational mode of treatment of enteric fever, and that β-naphthol is a safe and tolerably efficient agent for this end.

"2. That by its use in the above cases the duration of the disease was shortened, and the intensity of the symptoms directly arising from profound disturbance in the alimentary canal was lessened.

"3. That the tendency to the occurrence of splenic enlargement, albuminuria, and of secondary complications such as boils, abscesses, etc., of purulent infective origin, is diminished.

"4. That complete convalescence is more speedily and satisfactorily attained; and that there is less risk of a propagation of the disease to others.

"Finally, we must bear in mind that in some patients naphthol may excite so much gastric disturbance as to prevent its use."

Treatment of Tubercular Diarrhœa with Lactic Acid and Iodoform.

The effect of lactic acid on the diarrhœa of nursing infants is well known, while its efficacy in the tubercular ulcerations of the tongue and laryngeal disease is generally admitted. It would seem to be indicated on double grounds in the treatment of the rebellious diarrhœa of tubercular cases. Henri Huchard states in the *Revue Générale de Clinique et de Thérapeutique*, November 22, 1888, that he has for the last six months employed lactic acid in doses of from thirty to sixty grains daily in cases of tubercular diarrhœa, but that his results have been almost negative. In such cases he adds that he has frequently arrested the diarrhœa by the use of iodoform in small doses. MM. Sezary and Anne appear, however, to have been more fortunate with the use of the lactic acid, which they have administered in doses of from thirty even up to one hundred and twenty grains daily. It would seem that Huchard's failures are, therefore, attributable to the insufficient quantity administered, for these authors assert that in all cases marked improvement was noticed on the second day, and by the fourth or fifth day the stools had become perfectly normal. They cite in support of this statement nine cases, all of which were cured by this method, and with only one exception did the symptoms return after the cessation of the treatment. It is doubtful if such favorable results can always be obtained; the diarrhœa is so rebellious, and the means of combating it so restricted, that any addition to our means of controlling this affection must be gladly accepted.—*Therapeutic Gazette*, Jan., 1889.

Acute Chorea with Insanity.

At the meeting of the Nottingham Medico-Chirurgical Society, Dec. 7, 1888, Mr. Evan Powell related two fatal cases of acute chorea with insanity. The first was that of a lad, 19 years old, whose father died of phthisis, and whose mother had had acute rheumatism when young. The patient had suffered from some rheumatic symptoms, and had been subject to mental anxiety. The choreic movements began in the left arm, then spread to the left side of the face, and in three days attacked the right side; and on the chorea becoming general he became maniacal, and developed delusions of taste, sight, and hearing. On admission, the spasmodic movements were so strong that he was unable to stand. The heart's action was very rapid, 170 to the minute, and there was a loud systolic apex *bruit*. Temperature normal; urine: specific gravity 1,030, acid, with a trace of albumin. During the first three or four days he continued acutely maniacal, and his chorea only slightly abated; some rest, however, was each night procured by chloral. The movements entirely ceased during sleep. For the next ten days he made rapid progress toward recovery, his mind becoming calm and his movements almost disappearing, whilst he put on flesh at a very rapid rate, gaining one pound and a quarter daily for twelve days. At the end of this period he relapsed, all his symptoms returning in an acute form, and he died from exhaustion five days later. During his lucid interval he remembered all that had taken place throughout his attack. On *post-mortem* examination the brain was found in a state of general hyperæmia, with some effusion of lymph in the arachnoid over the motor areas. There were numerous vegetations on the mitral valve, the edges of which were thickened. The lungs were collapsed; the spinal cord normal to the naked eye.

The second case was that of a single woman, 20 years old. The patient had a good family history, there being no taint of rheumatism, heart disease, or nervous affection. She had never suffered any illness herself until about six weeks before admission, when the catamenia did not appear at the proper time, and she became much distressed about this; she placed herself under treatment, and in about three weeks later she had a sort of hysterical fit; four days afterward choreic movements began in her limbs and face, which gradually became more violent, and a fortnight after this symptoms of insanity showed themselves; she became maniacal, and had hallucinations of sight and hearing. On admission the patient was in a state of acute chorea, but her mania had somewhat abated; she was much exhausted. The spasmodic movements were general. There was no abnormal cardiac sign, except that the beat was very rapid—140 per minute; temperature 102.5°; she was menstruating. The choreoid movements gradually left her limb and trunk muscles, but continued in those of the tongue and pharynx, so much so that swallowing and speech were rendered very difficult; her mind also became calm and apparently clear. She gradually sank, however, from exhaustion, five days after her admission. On *post-mortem* examination the brain was found intensely hyperæmic,

but no other diseased condition was visible to the naked eye. The spinal cord was apparently normal. The heart showed slight thickening of one of the cusps of the mitral valve; no vegetations. The other organs were healthy. The uterus showed signs of recent menstruation. These cases show how important a part mental anxiety may play in the causation of chorea. Mr. Evan Powell believes the disease to be due to a condition of the blood, allied to, but not necessarily associated with, rheumatism and endocarditis.

Dr. Handford, before describing the microscopic appearances found in the two cases related by Mr. Evan Powell, gave a tabular statement of 154 cases which had been in the General Hospital within the last 14 years. From these, and from the very large number seen as out-patients, he expressed the opinion that chorea is unusually abundant in the Nottingham district. The table showed two deaths, and also that in the age and sex distribution the males were to the females as 1 to 2.4 before the age of puberty, and as 1 to 4.5 after that age. Thus the liability of the female sex, already unduly great, nearly doubled after the age of puberty. Dr. Handford further expressed the opinion that the endocarditis of chorea, when not rheumatic, is chiefly, if not entirely, of mechanical origin. The endocarditis, which was found almost, but not quite, invariably in fatal cases was of a special character. The numerous small vegetations, chiefly limited to the margins of the valves, with little, if any, general thickening, suggests that the invariable, abrupt, tumultuous, cardiac action in a generally anæmic subject caused a bruising of the valve margins where they came into contact, and thus started the endocarditis. He looked upon the endocarditis as a comparatively trivial complication, so far as its immediate effects were concerned. The microscopic appearances in Mr. Powell's cases were illustrated by numerous drawings, showing small hemorrhages, chiefly in the cord and pons, but also in the motor cortex; thromboses of vessels with hemorrhage into the lymph sheath; rupture of vessels in the commissure of the cord; and one vessel in which there was what appeared to be an incomplete embolus. No change was found in the nervous elements of the cord or brain. Dr. Handford expressed the opinion that all the symptoms of chorea are explicable on the hypothesis of a hyperæmia of the nervous centres, and he thought that this view is amply borne out by the camera lucida drawings he had shown. Chorea appears to be due in mild cases to a hyperæmia of the cord, and perhaps the basal ganglia, the lowest and middle evolutionary levels; and where the mind is affected and insanity ensues, the cerebrum, the highest level, has become involved.—*British Med. Journal*, Jan. 5, 1889.

One Thousand Consecutive Cases of Abdominal Section.

In the *Medical Record*, Nov. 10, 1888, Mr. Lawson Tait reports a general summary of conclusions drawn from a second series of 1000 consecutive cases of abdominal section. This series of operations has been done in the last four years, with a mortality of 5.3 per cent.; the mortality of his first series of 1000 cases was 9.2 per cent. The diminished mortality is attributed by Mr. Tait partly to the fact that he has freed himself from the shackles imposed by the traditions of the elders, partly to increased skill, and partly to the fact that the general profession is beginning to forsake the old, and to follow the new light; hence cases come to the specialist in better condition now than formerly. Two rules are insisted on: first, that the principles which govern our actions in general surgery must apply in abdominal surgery; and, second, that no doubt or difficulty of diagnosis should stand in the way of adopting that means by which the diagnosis is at once made clear, and successful treatment rendered possible by means of abdominal section.

He attacks the doctrine, attributed to Sir Spencer Wells, that an ovarian tumor should not be removed so long as the patient can go about; and maintains that an ovarian tumor should be removed as soon after it is discovered as possible.

In support of the claim to validity of exploratory abdominal section, the histories of two cases are given. The first case was one in which the attending physician diagnosticated simply "a lump in the pelvis," and for which lump he treated the woman "medically" three months, in which time she was brought to the edge of the grave. She was then sent to Mr. Tait for diagnosis and treatment. A large putrid sac of a ruptured tubal pregnancy was removed. The woman had not vitality enough left to recover, and died a few hours after the operation—a victim of an incomplete diagnosis. In the report of the second case the Drs. Keith, father and son, are attacked, more especially because of their opposition to the principle of exploratory abdominal section, and the

"restless spirit of abdominal surgery which has lately been let loose." Dr. Skene Keith had diagnosticated the disease as probably sarcomatous, and had recommended a stomach mixture, apparently for the patient's encouragement. When Mr. Tait was consulted, the patient had been twice tapped, and a large ascitic effusion was present. He considered the ascites due to an ovarian tumor jammed into the pelvis, and perhaps fixed by papillomata. An exploration was made, a small papillomatous cystic tumor of the right ovary found, and also secondary papillomata infecting the abdominal viscera. From the history of the case Mr. Tait concludes that papillomatous infection had not occurred when the woman consulted Dr. Keith—the inference being that had a correct diagnosis been made by exploratory section and the cyst removed, the woman would have been saved.

Fifty-three exploratory abdominal sections were made in this series, as compared with 94 in the first series. Exploratory incision is still preferred to first tapping, because a complete diagnosis is thereby possible, and the incision serves the purpose of a complete tapping; and also because, as the patients almost uniformly recover, the incisions do no harm. The smaller number of exploratory incisions is explained by the fact that the patients come to the operator earlier than formerly. Thus results are arrived at exactly the opposite of the disaster narrated in Dr. Skene Keith's case. At least 30 cases in this series, in which tumors have been removed successfully, would have resulted as did the case referred to had removal been delayed; an argument for early operations and for exploratory incisions which is perfectly unanswerable. Of these 53 patients, 2 died, but the operation neither hastened nor delayed this event.

Occasionally the exploration is followed by drainage, and in some of these cases the most marvellous results have followed—the ascitic effusion has not appeared again, and tumors of the spleen, liver, and other organs, the nature of which was not ascertained, have disappeared, and the patients have been permanently cured. No explanation is offered of this extraordinary fact, but its truth is undoubted.

The next group consists of 263 operations for chronic inflammation of the uterine appendages, with a mortality of 3.4 per cent., as against a mortality of 5 per cent., in the first series—a diminution which is attributed to increased experience. All the operations were completed. These operations are considered more difficult than the removal of tumors of any kind, and the deaths are almost entirely confined to the broken-down condition of the women—the "too late" cases of Mr. Bryant. Mr. Tait congratulates himself upon the fact that the profession and public have accepted his teachings concerning this class of disease. As evidence of this he has 263 cases to report in this thousand as compared with 201 in his first series.

The use of electricity in the treatment of inflammation of the uterine appendages is next considered. Those who claim to be able to cure gonorrhœal inflammation of the appendages are invited to cure gonorrhœal inflammation of the elbow and knee joints, and the promise is made that when the elbows and knees have been restored to their pristine state, more credence will be given to the assertions of cures of appendages infected with gonorrhœa.

Mr. Tait states that he has always maintained that the great majority of cases of inflammatory disease of the uterine appendages get well without operation, though getting well does not necessarily mean that they are cured. He contends, however, that the residuum should not be condemned to live on, hopelessly suffering, while there is a *dernier ressort* at command. When that should be invoked is a matter for determination in each particular case, and depends upon conditions which cannot be formulated into laws, varying as they do in importance, even to the social position of the patient. Electricity may yet prove the means of still further diminishing the number of cases to be submitted to the surgical method.

The treatment of uterine myoma by electricity is considered unsatisfactory and even dangerous. The treatment of myomata by removal of the uterine appendages is believed to be far safer and more satisfactory. The uterine appendages have been removed in 148 women suffering from myoma, with 3 deaths, giving a mortality of 2.03 per cent.; whereas there were 99 cases in the former series, with a mortality of 7 per cent. The two series include 247 cases with ten deaths. Three women subsequently died with cancer, 3 had hysterectomy performed owing to the subsequent growth of the tumor, but no other failures are known.

Eighty hysterectomies are reported with a mortality of 11.3 per cent.; a striking contrast to the previous series of 54 cases with a mortality of 35.7 per cent. This diminished mortality is attributed to the

adoption of Keith's method of operating. This method was not known to Mr. Tait until recently, because Keith would not allow him to witness the method of operating. The point is a simple one and consists in tying the broad ligaments separately, and stripping them off the uterus. This prevents occlusion of the rectum by taking off the strain. The fact that there have been 31 consecutive recoveries from hysterectomy shows that the mortality may be made to approximate that of ovariotomy.

Nothing is added to the method already published concerning the operations of cholecystotomy, nephrectomy, nephrotomy, opening and draining pelvic abscesses, and operations for tubal pregnancy.

Twenty-six cases of acute and chronic suppurating peritonitis were treated by abdominal section, washing out, and drainage, with only 4 deaths—a mortality of 15.3 per cent.; whereas there were nine cases in the first series with a mortality of 22.2 per cent. It is urged that these cases should be treated by early and efficient drainage, just as in purulent pleuritis.

Four cases of puerperal peritonitis have been operated upon, with 3 deaths. The operation is considered as on trial, but it must have a fair trial—must not be left as the closing scene. Mr. Tait believes that in many cases of puerperal peritonitis the chief trouble is in the womb, and that removal of this organ may be necessary to effect a cure.

The article concludes with a presentation of the claims of a modified Porro-operation, for which see the REPORTER, Jan. 5 and 12, 1889.

An Eruption from the Use of Sulphonal.

The employment of sulphonal as a hypnotic has been followed by an eruption in one case occurring in the practice of Dr. Engelmann (*Wiener medizinische Blätter*, November 1, 1888). The patient was a woman, 40 years of age, suffering from chronic metritis with violent dysmenorrhœic pains, in whom sulphonal was given to relieve the insomnia, after chloral had failed. Thirty grains of sulphonal were given at bedtime; no hypnotic effect was noted, but on the following morning a diffuse scarlet-red eruption appeared, accompanied by itching under both breasts. The red coloration of the skin was sharply separated from the normal skin and rapidly extended, so that on the evening of the same day it had covered the internal sides of both arms in a perfectly symmetrical manner, and reached to the sternum; on the morning of the following day it had extended to the abdomen, and the eruption, which had been distinct on the two sides of the body, was now confluent. On the third day the eruption, which was now the seat of violent itching, gradually disappeared. It has been noted by Lesser that in the majority of cases the production of eruptions from the use of drugs is to be explained as attributable to vaso-motor disturbances, a theory which in this case appears to be sustained by the perfectly symmetrical character of the eruption.—*Therapeutic Gazette*, Jan., 1889.

Dislocation of the Eyeball.

A singular case of dislocation of the eyeball is related by Dr. Van Dooremaal in the *Donders Fest Bundel.* A butcher's assistant, in passing out of the shop, caught his upper eyelid on one of the hooks. He begged his fellow-shopman to extricate it for him, but the latter performed his task so awkwardly, that the hook pushed the eye forward, and allowed both upper and under eyelid to disappear completely behind it; even the eyelashes were invisible. The man was brought to Dr. Van Dooremaal. The eye was pushed frightfully forward. The man shrieked incessantly, "Oh, how strong the light is"; and on being asked whether he was in pain, replied, "Yes, but oh, that light, that light!" while he clasped his hands convulsively over his eyes. Dr. Van Dooremaal decided to enlarge the external angle of the eyelids by means of blunt-pointed scissors, which were introduced between the protruding eyeball and the outer angle. After the cut had been made, a strabismus hook was introduced along the under edge of the upper eyelid. As soon as the hook had been pushed somewhat inward under the upper eyelid, a curette was inserted, and then pressed outwardly without exerting pressure on the eyeball, so as to bring the upper lid out. This was accomplished without difficulty, and then the under lid was gently drawn back to its place by the thumb. The wound was sewed up as usual, and the eyes bandaged. The wound healed quickly; the reaction was extremely small, but the patient complained of excess of light on the removal of the bandage. The discomfort, however, soon disappeared, and the sight was normal.—*British Med. Journal*, Jan. 5, 1888.

Case of Subacute General Anterior Spinal Paralysis.

MM. Pitres and Vaillard report in the *Progrès Médical*, Sept. 1, 1888, a typical case of the affection described by Duchenne under this title. The patient, a robust man 43 years old, took a violent chill, which was followed by shivering fits, a feeling of general malaise, colic, and tenesmus, with slight diarrhœa. A month later, another attack of the same kind came on, with extreme feebleness; and six weeks after the onset of the illness, he came under observation, complaining of general weakness. The muscular feebleness was very marked. Two days after admission, paralysis, without affection of sensation, came on in the right shoulder, and shortly afterward in the left. About a week later, the paralysis had extended to the arms, and to the muscles on the posterior aspect of the forearms. The patient now complained of great weakness in the legs; was barely able to stand, and could not walk at all. Seven weeks after admission, all motor power in the four limbs was completely lost. The muscles now began to waste, and to lose their excitability to the Faradic current in the order in which they had been involved in the paralysis. There was no affection of sensation of the sphincters, nor of the organs of special sense, and no fever. A month later, there was œdema of hands and of the lower extremities, but no albuminuria. Slight signs of bulbar paralysis now showed themselves, with nocturnal delirium. Two months afterward, the patient was in the same condition, except that he was beginning to gain power in the right arm: at this time he died of an attack of lobar pneumonia.

At the autopsy the brain and spinal cord were normal; the only abnormality found, on microscopic examination of the spinal cord, was a slight degree of thickening of the neuroglia in the lateral columns and in the columns of Goll. The peripheral nerves, both in the large nerve-trunks and in their finest ramifications, showed considerable morbid changes of the form described as "degenerative neuritis," differing in degree only, and not in the nature of the pathological alterations, in different regions. Briefly, the changes consisted in breaking up or segmentation of the myelin sheaths (early stage), followed by complete atrophy, leaving empty nerve-sheaths mixed with finely varicose fibrils. The proportion of healthy nerve-fibres mixed with the atrophied fibrils in the nerve-trunks was exceedingly small. These lesions affected without exception the nerve-trunks and their branches in the four limbs. The anterior roots of the spinal nerves were much less altered. Individual nerve-fibres were found to be affected in the same way as the foregoing; but there were few diseased nerve-fibres, and these occurred individually, scattered amongst the very much larger proportion of healthy fibres, whilst here the morbid process never destroyed whole bundles of nerve-tubes as it did in the case of the peripheral nerves.

The symptoms of this affection resemble those of Landry's paralysis; but differ in the slowness of onset and progress. Duchenne thought that the seat of the lesion would be found in the motor cells of the anterior cornua of the spinal cord. The case is interesting, since it shows that in this undoubted instance of the affection in question, the peripheral nerves were affected almost alone, the slight change found in the spinal cord being unimportant. It also shows that profound alterations in the mixed nerves may cause only general motor paralysis without any affection of sensation. The authors give a brief account of the few cases of this rare affection that have been published hitherto. — *Bristol Medico-Chirurgical Journal*, Dec., 1888.

On the Effects of Acids on the Functions of the Stomach, and Their Therapeutic Application.

W. Jaworski (*Ctrlblatt für klin. Med.*, 1888, No. 10) draws the following conclusions, after extensive experiments with acids on the gastric function:

1. The acids throw down a considerable precipitate of mucus.

2. They (especially hydrochloric acid) increase the cellular elements of the gastric contents.

3. Their introduction is followed by intense butyric reaction, most marked after hydrochloric acid.

4. Larger quantities of the acids produce a considerable effusion of bile into the stomach.

5. They stimulate, very actively, the secretion of pepsin, but have no more influence upon the secretion of hydrochloric acid than so much distilled water would have.

6. Their long-continued administration is followed by marked diminution of the secretion of hydrochloric acid.

7. Even in large quantities hydrochloric

acid produces no gastric disturbances. On the contrary, a continued administration of the acid is attended with a feeling of well-being.

8. The difference in the effect between acids and the alkaline salts on the gastric functions consists in the fact that the alkaline salts dissolve the mucus and decrease the secretion of pepsin, while the acids precipitate the mucus and increase the secretion of pepsin. The disappearance of the alkaline salts from the stomach is followed by a decided increase of the hydrochloric-acid secretion. This does not occur, or only to a slight degree, in the case of acids. Both the acids and salts, in large quantities in continued use, have the same effect in lowering the activity, and finally in destroying the function of the glands secreting hydrochloric acid.

Experiments with the introduction of carbonic acid into the stomach, either in gaseous form or dissolved in water, show that this acid has the property of stimulating the peptic and acid functions of the stomach, and in that way increases its digestive power. — *N. Y. Med. Journal*, Jan. 19, 1889.

Cellulitis of the Neck, with Partial Paralysis of the Right Arm, following Acute Traumatic Otitis Media.

Dr. Christopher Lewis, Assistant Surgeon of the Ear and Throat Hospital, Birmingham, reported a case of this kind to the Section on Otology of the British Med. Association, at its meeting in Glasgow, August, 1888. He was called in consultation to see a strumous, delicate boy, 13 years old, with the following history: some fourteen days before his visit the lad had received a box on the ear at school—a fact not brought before the attendant's notice. The patient complained of sore throat and occasional earache; in a few days these slight symptoms rapidly developed into a more serious condition, for the temperature ran up to 102°, delirium came on at night, obstinate vomiting and pain in the head were present. These symptoms became more pronounced, especially the delirium; deafness became marked, and the temperature ranged between 102° and 104°.

About the ninth or tenth day the true nature of the disease showed itself by a swelling and redness over the apex of the mastoid, and the cerebral symptoms, which had been gradually improving for a few days, almost disappeared. The mastoid puffiness subsided, only to be followed by a deep-seated inflammation of the neck, which rapidly assumed an alarming size. There was a slight muco-purulent exudation in the external meatus of the right side, which was generally congested and tender to touch, but no inflammatory thickening. The tympanic membrane had a boggy appearance, its lustre had gone, and the pyramid of light was obliterated; there was, however, no perforation.

The whole inflammatory mischief was now centred in the neck, where an enormous swelling had developed, as hard as a board. This induration extended to some distance beyond the edge of the sterno-mastoid posteriorly, anteriorly to the median line of the neck, inferiorly on a level with the clavicle, and superiorly in a line with the floor of the meatus. There was some difficulty in swallowing, and the breathing was slightly labored. Singularly enough, Dr. Lewis remarks, there was no history of rigors, nor was there the least tendency to pointing; the pain, however, was so great and the constitutional disturbance so grave that it was a matter for serious consideration whether or not some attempt should be made at once to relieve the pressure. It was decided, however, to wait a day or so. On his next visit, as the symptoms did not appear to subside, it was decided to make an incision, although no fluctuation could be detected. A point was chosen a few inches above the clavicle, and, dividing the skin and superficial fascia, a grooved probe was moved about until a caseous mass was at last struck upon. The wound was then enlarged, and after the caseous substance had reached the surface there was some discharge of pus. As the hemorrhage was rather profuse the wound had to be plugged firmly with strips of lint. The pus welled up freely during the night, and the following morning there was a decided improvement in the patient's condition, and from this time virtually the whole symptoms began rapidly to subside. Dr. MacMunn made a counter opening later on. It was at this stage that some difficulty of movement was noticed in the right arm, owing, of course, to the injury received by the cervical plexus. This in itself, Dr. Lewis thinks, is sufficient to show how deep-seated and extensive the inflammation was.

Owing to some trophic changes, the patient lost the nails from three fingers. He gradually lost his deafness, and his hearing is to all tests and appearances normal. The recovery is said to have been in every

way complete, although his convalescence was both prolonged and tedious.

In his remarks on the case Dr. Lewis says that the escape of pus through the mastoid in all probability saved the patient's life and prevented involvement of the brain, for, instead of bursting the membrane, the fluid forced its way into the mastoid cavity, and then through its apex, for it was at this point that the redness and swelling presented itself, and thus the products of inflammation were brought into contact with the deep cervical fascia, accounting for the formation of cellulitis.

Bezold was, he thinks, the first to point out that when the inflammation of the mastoid process is confined to the inner aspect of the apex of the mastoid, extension to the neck takes place, for a very thin osseous layer here protects the air-cells, so that, if any pus is formed, it easily forces its way through it at its inner aspect, and thus readily extends beneath the sterno-cleido-mastoid muscle, and so the pus escapes into the deep tissue. The time from the appearance of mastoid puffiness to the development of the enormous swelling in the neck could be counted by hours rather than by days. Deep-seated abscess not infrequently forms in the muscle of the neck near the affected mastoid cavity, but it rarely spreads so deeply as in the present case. Again, phlebitis of the emissory veins of the mastoid may occur in the course of an inflammation of the ear, but the induration is peculiar; and, although a cellulitis may develop, Dr. Lewis is not inclined to the belief that the case could be classified among those due to such a cause.

Death from the Presence of a Caseous Gland in the Trachea.

A healthy-looking boy, five years old, was admitted at 7 A. M. on Nov. 29, 1888, into St. Thomas's Hospital, under the care of Dr. Ord, suffering from great dyspnœa, lividity, and cough of four days' duration. According to the parents, he had coughed up a thick piece of phlegm the preceding night. Rhonchi were heard over both lungs. An emetic was given, and at 10 A. M. the child seemed fairly well. He continued well until Dec. 9, when he was discharged. During his stay in the hospital his temperature rose, once to 104° and at other times to 102°, for no apparent reason. On Dec. 18 he was readmitted to the hospital, suffering from still greater dyspnœa, especially well marked on expiration. Rhonchi were heard over both lungs, and the child was in very great distress. Stimulants and expectorants were administered, but he died at 2 A. M. on the 19th. At the post-mortem examination, held the next day, both lungs were collapsed, and there was a little inflammation of the bronchi. But in the trachea, just above its bifurcation, springing from the right side, was a caseating gland which had ulcerated through its walls and almost completely blocked it. A few more caseating glands were found round the trachea and bronchi, but none elsewhere. This is a very rare condition, inasmuch as the gland which caused the fatal result was found lying loose in the trachea, having been "shelled out" from the suppurating cavity. A similar case was recorded by Dr. Goodhart in 1879, and another by Dr. Percy Kidd in 1885. It is more common to find caseating abscess cavities communicating with the large air tubes.—*Lancet*, Jan. 5, 1889.

Cancer of the Womb in a Girl Eight Years Old.

F. Gaughofner reports a case of this kind in the *Zeitschrift für Heilkunde*, S. 337, 1888. He first refers to three cases of carcinoma of the uterus occurring in patients under twenty years of age, which have been reported by Schauta, Rosenstein and Eckart, and then gives an account of a case observed by himself. The patient was a girl eight years old, who for two or three years suffered with irregular hemorrhage from the vagina. On examination a large number of soft nodules were found extending apparently from the anterior vaginal wall. The patient was anæsthetized, and a speculum introduced. A tumor was found the size of a hazel-nut, which bled when lightly touched. The tumor was pronounced a sarcoma of the vagina. On Dec. 14, 1887, the sphincter of the vagina was cut posteriorly, a large speculum introduced, the tumor excised with scissors, and its base destroyed with the thermo-cautery. On Dec. 15, fever set in; on the 16th the iodoform bandages were changed, when it was demonstrated that the excised tumor arose exclusively from the portio vaginalis. On Dec. 17 variola developed, and the patient succumbed Dec. 25.

At the autopsy no more tumors were discovered. Microscopic examination of the tumor proved it to be a medullary glandular carcinoma of the portio vaginalis.—*Centralblatt f. d. med. Wissenschaften*, Dec. 15, 1888.

Recent Observations Relating to Intubation.

Dr. Francis Huber, chief of the Clinic for Diseases of Children, College of Physicians and Surgeons, New York, read a paper on Recent Observations relating to Intubation of the Larynx, before the N. Y. Academy of Medicine, Oct. 24, 1888. This paper is supplementary to one read before the Academy June 2, 1887, and is published in the *Archives of Pediatrics*, Jan., 1889. He states that of 94 cases there have been 37 recoveries; about 40 per cent. Patients over three years of age numbered 45; of these 20 recovered—about 44½ per cent.; while of the 49 under three years of age, 17 recovered—about 35 per cent. This he very properly regards as a favorable showing, especially when it is borne in mind that the larger proportion of the cases occurred in thickly-populated districts under the poor hygienic and sanitary conditions existing in tenements. The cases were not selected. Intubation was resorted to no matter what complication existed, when the stenosis became sufficiently grave to warrant operative interference. He states also that they were late cases.

As regards the time for performing intubation, Dr. Huber says he does not favor early operation, because he has seen a comparatively large number of patients recover under the faithful employment of the bichloride of mercury and steam.

The difficulty in feeding, the strongest and most valid objection to the method, may be overcome in great measure by the employment of a trained nurse, personal supervision on the part of the physician (the idiosyncrasies of each patient as regards the ability to swallow liquids being carefully studied), the use of solid and semi-solid nourishment, rectal or forced feeding through the stomach-tube by the mouth or nares, and intermittent intubation.

If the symptoms in a case lead to the belief that the trouble is localized in the larynx and trachea, a full-sized tube should be inserted. A smaller tube may be inserted (with a view to being coughed out after a variable period of time) when membrane is suspected in the bronchi, or to relieve the recurring dyspnœa occurring in some cases upon the removal of the larger tube at the fourth, fifth, or sixth day.

Intermittent intubation, he says, offers the following advantages: Food, medicines, and stimulants may be administered in the interval. If membrane exists or is loose below the tube, there is less danger of occlusion, for the tube is readily coughed out, and with it the membrane. The time of wearing the tube is materially shortened. The spasm which sometimes occurs when the larger tube is removed on the fourth to the sixth day is relieved by the insertion of a smaller tube, and when the latter is coughed out, usually in from six to twenty hours, the patient will be found to breathe without difficulty.

He asserts that his deductions are not theoretical or imaginary, but are based upon numerous and careful observations, verified in a number of cases. He admits that intermittent intubation has been advocated before, but the plan proposed differs from the one he uses, in that the tubes (full sized) were removed at intervals and reinserted after the child had been fed. Dr. O'Dwyer, in detailing his second series of cases, incidentally refers to the advantages afforded by employing smaller tubes in certain cases. Dr. Huber's investigations in this respect were conducted without a knowledge of what had been accomplished by Dr. O'Dwyer.

Nasal Bougies.

Dr. H. C. Wood states in the *Therapeutic Gazette*, Jan. 15, 1889, that having had a severe case of hay-fever in his own household he was led to make experiments upon nasal bougies. He tried gelatin without success. When fresh, bougies made of it have not sufficient stiffness to be inserted into a partly occluded passage, but in a few days they become so hard as to be distinctly irritating. Cocoa-butter seems to be free from objection, though some skill is required to make bougies of it when it is used alone. The employment of wax is altogether objectionable.

If the patient is lying down, the bougie should be pushed forcibly upward, so as to jam itself between the two sides of the upper nostrils, closed by the swelling of the erectile tissue; it will then be held firmly in place, and in a few minutes will melt. After the insertion of the bougie, the patient should continue to lie down, with a pledget of absorbent cotton wet with cocaine pushed up the nostril, so as to prevent the cocoa-butter as it melts from running over the lip.

The only medicine that Dr. Wood has found of service in hay-fever is cocaine, which, he says, seems to act better when added to a little atropine. Each bougie should be made to contain one grain of hydrochlorate of cocaine and one-twentieth grain of atropine.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

A CONFIDENTIAL WORD TO OUR READERS.

It is with much pleasure that we acknowledge the gratifying response of our subscribers to the effort of the publisher of the REPORTER to get the mail-list in first class shape. There is a great difference between the cleanness of the mail-list to-day and the state in which it was nearly two years ago. There were on it then names of men who had not paid up for some time, and who apparently never meant to. These have been asked to pay, then asked more firmly, then drawn on, and then—if they did not settle—they have been cut off. There were on it also the names of men who had asked to have it stopped. These it took some time to discover. But the work of straightening things out has gone on steadily, and now the mail-list is one which can be regarded with great satisfaction by all the real friends of the REPORTER. It is larger than ever within our knowledge, and the subscribers seem to share the opinion of the publisher that good business principles are the best all the time.

It may surprise some of our readers to know that it has been necessary to part with a certain number of subscribers who had been getting the REPORTER at a reduced rate, for no other reason than that they were not willing to pay the usual price. This unjust discrimination is no longer made; and those who regard the REPORTER as a first-class publication, and treat it as such, will be pleased—we trust—to know that the publisher endeavors to treat all who have business dealings with it exactly alike. This applies to advertisers and subscribers both; and we can heartily recommend each of these classes of our patrons to the other; in the full belief, from our own relations with them, that both are honorable and upright, and that it is to the advantage of both to be brought into such relations as a medical journal may properly secure. In saying this, we desire to thank all those—both subscribers and advertisers—who have seconded our efforts to make the REPORTER a good medical journal, and promise—so far as our judgment shall extend—to keep it honest, impartial and fearless. We shall take kindly any friendly corrections which may be offered, and hope for continued support in every endeavor to do what is right.

AN ARTIFICIAL BLADDER.

Among the recognized operations of surgery total extirpation of the urinary bladder is one of the most formidable, and most rare; but it is performed often enough to make it desirable to have some way of providing a receptacle for the urine which will measurably, at least, obviate the inconveniences of a continuous discharge from the

ureters. Up to a very recent date the best method consisted in turning the ends of the ureters into the rectum, and imitating the mechanism found in birds. The most successful experiments in this direction with which we are acquainted are those of Novaro, of Siena, in Italy, who carried the operation out in two sittings. More recently Tizzoni and Foggi, of Bologna, have on June 22, 1888, tried a new way of replacing the bladder, which consisted in isolating a portion of the small intestine, by dividing it at intervals of about two and a half inches, leaving its mesenteric attachment undisturbed, suturing its two ends so as to make a closed cavity, and joining the two ends of the intestine itself, so as to restore its continuity. At a subsequent sitting, about a month later, the ureters were separated from the bladder, and the latter was excised. The ureters were then inserted into two incisions in the now somewhat contracted cavity of the section of intestine and were stitched in place, while the lower end of the new receptacle was incised transversely and the edges of the incision were carefully stitched to the stump at the neck of the bladder.

The result of the operation, which is fully described in the *Centralblatt für Chirurgie*, Dec. 15, 1888, was entirely satisfactory. After a short period of relative incontinence, the new bladder began to perform its office in a very excellent manner, and the dog was able to hold its water for an hour or more and to pass it naturally.

This interesting experiment indicates that it is possible to obtain in animals an organ lined with mucous membrane and surrounded with a muscular wall, as a substitute for the urinary bladder in cases in which this has to be removed or in which it cannot perform its usual functions. It may be that the experiment would not prove so successful if performed on a human being; but the result obtained on a lower animal encourages the hope that it may be possible to extend its benefits to mankind as well.

THE PHILADELPHIA HOSPITAL.

There are few persons, not officially connected with the Philadelphia Hospital, who are aware of its value as a place of refuge for the sick and injured, and as a teaching institution. The service of the staff of this hospital will compare favorably with that of any hospital in this city, and the results obtained are as good as is usual in hospitals, and wonderfully good in view of the character and physical condition of many of the patients, and the arrangement of the buildings.

These facts, added to the fact that in the Philadelphia Hospital almost all of the students of medicine in this city receive a considerable part of their clinical education, are sufficient to attract to it the attention of the profession as well as of the citizens at large.

Just at present this attention is especially keen because an effort is being made by those who are interested in the Hospital to increase its dignity and improve its opportunities for usefulness by freeing it from an element which has always been a source of prejudice against it on the part of those who might enjoy its hospitality, and an obstacle to securing the best results of the work of its staff of physicians and nurses. This element is the presence of thousands of paupers in the vicinity of the hospital wards. The hospital was originally but an adjunct of the Philadelphia Alms-House—its Infirmary, in fact; but it has grown now to be a large municipal Hospital and its importance as a Hospital and as a teaching institution requires that it shall now be treated as a distinct establishment, and freed from the embarrassments caused by its attachment to the parent institution.

All of the friends of the Hospital—and, we may say, of medical education in Philadelphia will be pleased to know that there is a good prospect that the authorities of the City will soon take steps to remove the Alms-House to some place better suited to the requirements of its inmates, and make

the alterations needed to complete the organization of the Hospital on an entirely independent basis.

It is to be hoped that all of our fellow citizens will share the unanimous opinion of the members of the medical profession that this step is a most desirable one, and aid those who are trying to have it carried out, by their personal influence and co-operation.

STATE ASYLUMS OR ALMS-HOUSES FOR THE INSANE.

The care of the insane has been the subject of a number of Communications and Editorials in the REPORTER during the past two years, and it is one to which attention will be called as often as occasion seems to demand.

Just now it seems proper to say a few words in regard to it, because the Governor of Pennsylvania in his last message to the Legislature has recommended a step which is directly opposed to principles which we have advocated in the REPORTER for April 14, and May 12, 1888. The Governor recommends relieving the crowded condition of certain of the State Hospitals for the Insane by sending part of their inmates to the County alms-houses. This is a suggestion which is opposed to the opinion of all who have made the care of the insane a matter of special study, and its adoption would be a step backward toward the customs of fifty years ago. Last April we cited the evidence on this subject presented to a Committee of the Senate of New York and especially that given by members of the New York Charities' Aid Society, showing that the pauper insane are not as well cared for under the jurisdiction of county authorities as they are in establishments under the management of the State. In May we cited the opinion of the State Lunacy Commission of Pennsylvania that State hospitals are much preferable to alms-houses for the care of the insane.

The recent recommendation of the Governor of Pennsylvania is the subject of an extended article in the *Pittsburgh Commercial Gazette*, January 7, 1889, part of which gives the opinion of Dr. C. C. Wiley, of Pittsburgh, and all of which we can endorse as reflecting the humane and scientific views in regard to the care of the insane which prevail among medical men at the present day.

We invite the attention of the readers of the REPORTER all over the United States to this matter, because it concerns them all. In Pennsylvania it merits immediate notice, because an unwise step might be taken at any time, unless its true character is made clear to the Governor and the Legislature, which is now in session. But it deserves notice everywhere, because a similar step may be next proposed when it is least expected. A year ago the Legislature of New York considered and refused to pass a bill to transfer the care of the insane to the State hospitals, and we spoke in support of that measure little thinking that before a year had passed we should be called on to protest against a proposition to degrade Pennsylvania to a level from which good and true men were then trying to elevate New York.

So our readers may bear in mind that the question which is of such immediate urgency in the State just now may at any moment confront them, and they may as well prepare to meet it when it comes, and lend their assistance to those who are facing it now.

PHILADELPHIA POLYCLINIC.—Among the interesting signs of enlargement of the scope of the Philadelphia Polyclinic we note the fact that its Trustees have founded a chair of Diseases of the Mind and Nervous System, and have elected Dr. S. Weir Mitchell to the Professorship. The prosperous condition of the institution is further indicated by the announcement of the purchase, for twenty-five thousand dollars, of a large property on Lombard Street above Eighteenth.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

LECTURES ON ECTOPIC PREGNANCY AND PELVIC HÆMATOCELE. By Lawson Tait, F.R.C.S., Edin. and Eng., LL.D., Professor of Gynecology in Queen's College, Birmingham, Surgeon to the Birmingham and Midland Hospital for Women, etc. Octavo, pp. 107. Birmingham: The "Journal" Printing Works, 1888.

At this time when the subject of ectopic pregnancy occupies the attention of the profession to a considerable degree, any contribution to the subject is very welcome. This is especially true when the contributor has had the large and exceptional experience of the author. In these lectures Mr. Tait gives his views concerning the nature and natural history of ectopic pregnancy, and his experience in the management of these cases, together with a cursory review of some of the literature of the subject in an entertaining but rather rambling manner. The allied subject of hæmatocele is also discussed. Bernutz and Goupil are quoted as having made the first important contribution to the literature of pelvic hæmatocele. This is striking. Bernutz was perfectly familiar with the true nature of pelvic inflammation and abscess, but it remained for Mr. Tait to discover the method of cure. And now the same is true of hæmatocele—more especially hæmatocele caused by the rupture of a tubal pregnancy.

While all may not agree *in toto* with Mr. Tait, his extensive and successful experience in the management of ectopic pregnancy demands and will ensure a wide circulation of these "Lectures" among all students in this field.

QUESTIONS AND ANSWERS ON THE ESSENTIALS OF SURGERY: TOGETHER WITH A FULL DESCRIPTION OF THE HANDKERCHIEF AND ROLLER BANDAGES. By Edward Martin, A.M., M.D., Instructor of (sic) Operative Surgery, University of Pennsylvania, etc. With ninety illustrations. Small 8vo, pp. 314. Philadelphia: W. B. Saunders, 1888. Price, $1.00.

Dr. Martin's book contains a very good summary of what may with propriety be termed the essentials of surgery. It is—as the title indicates—arranged in the form familiar to all who have enjoyed the benefits of a "quiz"; and the questions and answers are clear and concise. In most respects it is thoroughly reliable. In some it is open to improvement. In the examination which we have been able to make of it, we have been struck with the inadequate consideration of fractures at the elbow-joint, and the omission of certain points in the treatment of impacted fractures of the neck of the femur which we regard as of great importance. It would be too much, perhaps, to expect a book like this to mention properitoneal hernia; but it would be an advantage if it did. The description of suprapubic lithotomy is also open to criticism.

We have made these comments not to disparage the book before us, but rather to suggest improvements in subsequent editions. As a whole we can heartily recommend it; for it contains, in a comparatively small space, a great deal of valuable surgical teaching. Its style is interesting, and its illustrations are admirable. On its general appearance, we can congratulate its publisher as well as its author.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

198. The Yellow Fever Panic. By J. C. Le Hardy, M.D., Savannah, Ga. 14 pages.

199. Consequences of Acute Suppuration of the Middle Ear, with special reference to Opening the Mastoid. By A. R. Baker, M.D., Cleveland, Ohio. From the *Transactions of the Ohio State Medical Society*, 1888. 20 pages.

200. Heart with Three Cavities. Partial Transposition of Abdominal Viscera. By M. Howard Fussell, M.D., Manayunk, Philadelphia. From the *Medical News*, Nov. 3, 1888. 11 pages.

201. The Homing Instinct. An Explanation Suggested. By George M. Gould, M.D., Philadelphia. From *Progress*, October, 1888. 24 pages.

202. Solution of the Philadelphia Water Question. By Emile Geyelin, Philadelphia. 7 pages.

203. A Contribution to the Study of Bone Repair. By John S. Miller, M.D., Philadelphia. From the *Transactions of the Philadelphia County Med. Society*, June 27, 1888. 7 pages.

204. The Treatment of Peritonitis by Abdominal Section. By L. S. McMurtry, M.D., Danville, Ky. From the *Annals of Gynecology*, September, 1888. 16 pages.

205. A Case of Typhlitis, with Double Perforation of the Cæcum, and Peritonitis, in which Laparotomy and Suture of the Gut were followed by Recovery. By L. S. McMurtry, M.D., Danville, Ky. From the *Journal of the Amer. Med. Association*, July 7, 1888. 8 pages.

198. In an Editorial in the Reporter, Jan. 5, we have already cited some of the views expressed by Dr. Le Hardy in his pamphlet on the yellow fever panic of 1888; but our readers will find it to their profit, we believe, to make themselves acquainted with the whole of it. There is much instructive reading here, and much which, if taken to heart, would tend to prevent the repetition of follies committed during 1888, which were of the most damaging character. Dr. Le Hardy has had opportunities of studying yellow fever such as few men can enjoy, and what he writes has the impress of great sense and judgment.

199. Dr. Baker's pamphlet is one which might well be studied by every medical practitioner. He dwells upon the importance of early recognition of suppurative disease of the mastoid and early and vigorous treatment of it. This he does with an earnestness which is fully justified by the fact that many lives are lost every year because the principles which he inculcates are not appreciated as they should be. He describes clearly the best method of operating upon the mastoid process, and gives accounts of a number of cases in which he himself has performed the operation.

200. Dr. Fussell describes the appearances in a case of malformation of the heart, in a child that died when nearly two years old, in which there was practically but one ventricle and one auricle, the other

corresponding parts being very imperfectly developed. The description of the specimen is preceded by an account of the history of the case from the birth to the death of the little patient, which forms a very interesting part of the paper and one of great practical value considered in connection with the findings of the autopsy. Cases of this kind are exceedingly rare, and such a carefully observed and described one is of unusual interest and instructiveness.

201. Dr. Gould's little pamphlet contains a number of interesting stories about the return of various animals to places from which they had been removed, and the suggestion in regard to the homing instinct is that it depends upon some unconscious relation between the animal and the magnetic currents of the earth. The author recognizes the purely speculative character of his suggestion, and invites experiments to test it which he has not yet been able to make himself.

202. Mr. Geyelin has for years been an interested student of the condition of the water-supply of Philadelphia, and has come to the conclusion that, for this city—as for all cities—it is important that sewage shall not be poured into the rivers from which the drinking water is obtained, and that the latter should be filtered to free it from solid matters held in suspension in it.

203. Dr. Miller describes two cases of bone repair occurring in his practice, in one of which the cavity of an involucrum of the tibia seemed to become filled with bony tissue, while in the other a button taken by trephining from the lower jaw bone, after removal of the periosteum, became consolidated when restored to its former position, although rotated through an arc of ninety degrees.

204. Dr. McMurtry describes a case in which opening the abdomen and washing out the peritoneal cavity led to great and long continued amelioration in the condition of a woman whose peritoneum was found to be studded with tubercles, and another in which he removed the ovaries and an offensive blood clot. Both patients are examples of the advantages of laparotomy in the treatment of peritonitis, when done according to the methods now approved by the best surgeons.

205. Dr. McMurtry reports the case of a physician upon whom he performed a laparotomy, and found two gangrenous perforations of the cæcum. These he treated by trimming their edges and suturing them. The patient made a good and uninterrupted recovery.

The history of this case is well described, and is of exceptional interest, because the case is the first on record of such an operation for the relief of non-traumatic perforation of the cæcum.

Literary Notes.

—A new German medical journal has just been started in New York, with the title *Medicinische Monatsschrift*. The first number is dated January, 1889, and contains 56 octavo pages of reading matter. It is edited by Dr. A. Teibert, and published by the Medical Monthly Publishing Company. The January number contains a good deal of interesting reading. The Editorial entitled "Unsere Berechtigung" has a boastful tone which we hope to see modified; but the magazine as a whole has a strong and incisive character, and is both interesting and instructive.

Correspondence.

"Good Form" in Doctors' Cards.

To the Editor.

Sir: Will you kindly say what is good form for the cards of physicians, both for office and social use? Should either contain "M.D.," and if the doctor is "F.R.C.S." may the letters follow his name? If "M.D." may be used, may "(Jefferson)," "(Univ. Penna.)" or "(Harv.)" follow? May the visiting card contain the office hours? I do not wish to start a discussion, but to know the usage of the *élite* in the profession.

Yours truly,

Country Doctor.

[The visiting cards of physicians are usually engraved with the full name preceded by the letters *Dr.* and with the street address in the lower right hand corner. Business cards are rarely used by physicians in the city; but when used they ought to bear the address and office hours.

It is not usual to have a visiting card contain any titles except as stated above. Business cards may contain the letters referred to, or others of like character, or the abbreviation for the place of graduation in medicine.—Ed. Reporter.]

Advertisement of a Physician.

To the Editor.

Sir: Herewith I send you an exact copy, *verbatim et literatim* (except name) of a card which is being circulated *in extenso* by a young would-be disciple of Æsculapius, and his agents, at various places in the neighborhood, more especially at church.

> Dr., What Is Your Bill?
>
> Visits . . . . . 75 cents
> Plus 15 cents per mile and first cost of medicine.
> Obstetrics: $5.00, and two extra visits.
> Consultation $5.00
> One dollar extra is charged for the night.
>
> —— ——, M.D.

This is certainly as unique as it is indefinite, and a good specimen for your "curiosity box," as showing one of the means of advertising which may be resorted to by the unscrupulous, in an extremity. It is perhaps proper to state, in justice to the character of the Greene County Medical Society of Pa., that the author of the card is not a member, although a resident of said county.

Yours truly,

Regular.

Greene Co., Pa.,
Jan. 19, 1889.

Typhoid Fever, its Care and Treatment.

To the Editor.

Sir: The communication of Dr. B. M. Smith, of Parsons, W. Va., in the Reporter, Dec. 17, 1888, regarding his experience with typhoid fever leads me to make the following remarks as to the proper management of cases of this disorder. The first step should be a free and thorough disinfection of every house where there is a case of the fever, while especially care is taken to render the dejecta innocuous. The general treatment of the patient should consist in sponging, once in twenty-four hours with a weak solution of permanganate of potash—about a violet color; of course tepid water is desirable, as it is more agreeable to the patient. The medical treatment is not of much importance, and is simple in application. First, of the patient. To reduce the temperature, the administration of three or four doses of eight or twelve grains of antipyrin usually has the desired effect. Then the following has proved very satisfactory in my hands.

℞ Tr. Iodi . . . . . f℥iii
Ac. carbolic . . . . . f℥ii

Sig. Three drops in a tablespoonful of water every two hours.

If there is any malarial complication, I frequently combine, in pill form, the following:

℞ Quininæ sulph. . . . . gr. xxiv
Acidi arseniosi . . . . . gr. i
Ferri carb. . . . . gr. xxiv
M. Div. in pil. No. xvi.

Sig. One every three or four hours.

The employment of the latter prescription is seldom required, the carbolic acid and iodine, when employed with plenty of cold water to drink and judicious feeding, is probably all the treatment that a typhoid patient will require.

Dr. Da Costa lays much stress on the early morning food; he advocates plenty of milk, broths, beef-tea, etc., and says they must be given *early* in the *morning*, say at two or three o'clock A.M. I have found this early morning feeding to be of incalculable benefit. In the later stages, during the third or at the beginning of the fourth week, the heart will be found weak and crippled from excessive work. So lame will this organ become sometimes that it will intermit in its systolic effort, dropping one beat in three, thus claiming eight hours of rest in the twenty-four. The pulse may be found very weak and intermitting, probably imperceptible at the wrist. The heart flutters and apparently is about to stop. In this condition no time should be wasted, lest the patient die. This heart must have a crutch to hobble on, and that crutch is alcohol; and whiskey is probably the best form in which to administer it. The quantity must be regulated by the effect. Thus, with the temperature under control, plenty and suitable liquid food at the proper time, and the heart sustained with alcohol, there need not be much fear regarding the prognosis.

Yours truly,
J. C. Ellis, M.D.

Philadelphia,
January 18, 1889.

Heroic Method of Removing Gunpowder from the Face.

To the Editor.

Sir: On the evening of November 10, 1888, a boy, 12 years old, came into my office with his face looking hideous by having a few moments before had gunpowder blown into it. Having always failed with the ordinary means, recommended and used in such cases, to obtain pleasing results, I decided to do nothing until festering had taken place, and then vigorously to rub it out with a very coarse towel wet with warm water. This, at the expiration of twenty-four hours, I satisfactorily accomplished in about ten minutes, and to-day there is hardly a vestige or mark of powder to be seen on the boy's face. I report this method of treatment because I have never read or heard of its being used before.

Yours truly,
John Gray, M.D.

Mystic River, Conn.

—The *Ledger*, January 15, 1889, says that an opinion has been rendered in the case of Frank H. Dent, plaintiff in error, against the State of West Virginia. Dent was convicted of unlawfully engaging in the practice of medicine without a diploma, in violation of a statute of the State. Dent appealed to the State Court of Appeals, asserting that the act was unconstitutional, inasmuch as it deprives him of liberty and property without due process of law, contrary to the Fourteenth Amendment to the Constitution. The Court of Appeals gave judgment against Dent and the Supreme Court has affirmed that decision.

Notes and Comments.

Hemorrhagic Variola.

In a communication in the *Archives générales de Médecine*, Dec., 1888, F. de Grandmaison gives an interesting account of hemorrhagic variola as observed in Paris in 1887. After remarking that the cases of hemorrhagic variola were furnished by the most infected quarters of the city, he states that there are two forms of this variety of smallpox, differing both in their symptoms and in their terminations. One is relatively benign; this he designates as cutaneous hemorrhagic variola. The hemorrhages take place only into the pustules; the general symptoms are not grave and improve in a few days; the eruption is discrete, the suppuration is slight, and the termination rarely in death.

The other form is grave, almost fatal. It is characterized by multiple, profuse, repeated hemorrhages; by marked general symptoms, which grow progressively worse; by very characteristic visceral complications; by a rapid course and generally fatal ending. This is true hemorrhagic smallpox. The physician should always have in mind these two forms of hemorrhagic variola, so as to be guarded in his prognosis, and not be exposed to unfortunate surprises.

Antipyrin in the Pains of Labor.

Auvard and Lefebvre have been unable to convince themselves of the far-famed action of antipyrin in the pains of labor. They tried it in ten cases in the maternity of the Paris Charité. Only three patients showed the effect of antipyrin; of these a marked relief was produced in one, and a slight relief in two cases; in seven the effect was *nil.* The solution used by them is as follows:

Antipyrin	gr. cviii
Muriate of cocaine	gr. iss
Distilled water	f℥ v

A syringeful, containing four and one-half grains of antipyrin, was injected three or four times.

In reviewing this experience, a writer in the *Wiener med. Presse*, Nov. 11, 1888, remarks that in a case of his own fifteen and one-half grains of antipyrin internally and the same amount hypodermically had not the slightest influence upon the intensity of the labor pains.

Care of the Insane in Pennsylvania.

That portion of Gov. Beaver's message which condemns the policy of sending the indigent insane from county almshouses to State asylums is being severely criticized, especially in this Western part of the State. The remedy he recommends—that of returning this class of insane to the county institutions and suggesting that the Board of Charities be empowered to insist on the proper maintenance of them, does not meet with the general approbation of persons interested in that branch of charity.

A remedy for the overcrowded condition of Dixmont, the State asylum in this portion of the State, has been suggested and is embodied in a bill which is being drafted under the supervision of Chief Elliott, of the Department of Charities. This bill which will be introduced into the Legislature at an early day will provide for the erection of a hospital for the insane, to be located in this county, and to be for the use of the contiguous counties of Beaver, Lawrence, Washington and Butler. The idea is to accommodate the indigent insane in this institution, and thus relieve Dixmont, which at present is overcrowded and cannot admit any more patients. This bill is gotten up for the relief of the poor insane whose friends are not able to support them in private asylums, and for whom there is no room in State institutions. It is a humanitarian move, as the fact can not be disputed that cases of this class can not be properly treated in a county or township home. The facilities of treatment in almshouses are very limited, and justice cannot be done the patients.

This bill will be supplemented by another now in course of preparation, or it may be that the two will be merged into one. The last bill recommends the erection of a hospital in the western part of the State for the maintenance of acute, or curable, cases of insanity. The object is to remove all cases of this class from the present State institutions and leave the latter solely for the accommodation of chronic cases. By so doing, and with proper arrangements, which will be specified in detail in the bill, the acute cases can receive immediate and positive attention from experts, and every facility offered that would tend to their rapid restoration to reason. Both these bills are intended as a remedy for the present state of affairs which is lamented by the Governor, and for which he proposes the relief mentioned above.—*Pittsburgh Commercial Advertiser*, Jan. 7, 1889.

Solidified Petroleum Fuel.

According to the *Revue Scientifique*, the problem of reducing petroleum to a solid state, available for practical purposes, has been solved by Dr. Kauffman, who has followed up the experiments made in the United States with the admixing of soap. He heated the liquid, to which from one to three per cent. of common soap had been added, half an hour, until the soap was completely dissolved, when the mixture acquired the consistency of tallow. The article thus obtained may be cut into pieces of suitable size for feeding to furnaces. Solidified petroleum, although it does not kindle readily, burns slowly and steadily and without smoke. The residual ash amounts to only two per cent. The combustion is only one third as rapid as that of an equivalent of anthracite coal, while the amount of heat evolved is more intense.—*Sanitarian*, Oct., 1888.

Absolute Signs of Death.

At the meeting of the Medical Society of London, December 10, 1888, Dr. B. W. Richardson read a paper on the absolute signs of death, which he took up in the following order: 1. Respiratory failure, including absence of visible movements of the chest, absence of respiratory murmur, and absence of watery vapor from the breath; this test is, he said, a fallacious one, for apparent movement and murmur might be absent, and the mirror test is useless. 2. Cardiac failure, including absence of arterial pulsation, of cardiac motion, of cardiac sounds, and absence of turgescence, or filling up of the veins on making pressure between them and the heart. The pulse as a sign is of more value than the cardiac motion or sounds, and yet even it may be undetectable, although the body may be alive and capable of recovery. He had written a paper some time ago on the maintenance of life when the circulatory apparatus was working at low pressure. An animal under chloroform may pass into this condition, the heart being only partially filled and emptied at each beat, and yet this partial action is sufficient to keep the animal alive, though scarcely any of the signs of life may be manifest. This cataleptic, syncopal, or hibernating condition is seen in animals while in a state of suspended animation. The proof by pressure on the veins was one not likely to deceive. A band should be bound round the wrist, a cardboard being arranged in front so as to relieve the arteries from pressure. If life were not extinct, turgescence of the dorsal veins of the hand would soon be apparent. 3. Reduction of the temperature of the body below the natural standard. A diminution of a few degrees does not signify death, as recovery has taken place even after a falling of the temperature to as much as 7° F. below normal. A fallen temperature as a proof of death should always be considered only in combination with others. If the temperature within the mouth were found lower than that of the surrounding atmosphere, it would be a strong presumptive sign of death. 4. Presence of rigor mortis and muscular collapse. Rigor mortis may be imitated by rigidity from cold or by tetanus, but the history will distinguish, and tetanic spasm produces distortion of the limbs. 5. Coagulation of blood in the veins. This, when present with rigor mortis, is an absolute sign of death, but both may be absent for even a long period. 6. Presence of putrefactive decomposition. Its presence in the eyeball indicates certain dissolution; but it is not in all animals an invariable sign of death, for frogs have been kept by amyl in a state of suspended animation until the web of the foot had commenced to decompose, and yet the animal has recovered. 7. Absence of red color in semi-transparent parts under the influence of a powerful light, such as that from a magnesian lamp. 8. Absence of muscular contraction under the stimulus of an electric or galvanic current. The handiest apparatus for this test is a small Faradic battery, and needles should be thrust into the muscles of the forearm. 9. Absence of a red blotch under the skin after the subcutaneous injection of ammonia. This test the author looked on as especially valuable. 10. Absence of signs of rust—oxidation—of a bright steel needle after plunging it deep into the tissues. This test is only of value for a short time after death, as later rust will follow from oxidation of the needle by the acid products of decomposition.

In the last part of his paper Dr. Richardson indicated the precise mode in which the practice named should be directly applied, taking up the steps of the necessary examinations one by one, pointing out the relative values of each, and giving, so to speak, in a condensed form, the diagnostic formula for an absolute proof of death in every doubtful case, without any operative procedure that was itself inimical to life. He recommended the practical application of tests in the following order:

1. Apply the fillet to the wrist and examine the veins at the back of the hand. 2. Open a vein at the bend of the elbow and seek for stringy coagula; open, if necessary, two or more veins. 3. Apply the electric test. 4. Inject ammonia hypodermically. 5. Examine by strong light for absence of red color from the transparent tissues. 6. If any doubt still remained, and rigor mortis had not developed, let the body be kept in a damp room at 84° F.; this would speedily bring about decomposition if the body were dead, and would favor recomposition or restoration if life were not extinct. This last test had the great recommendation that it could be carried out in those cases where it was forbidden to touch the body.

Dr. C. H. F. Routh said he had observed in persons dying from pneumonia, especially if the disease were double, a remarkable preservation of natural color. He referred to a case under his care in which, after death following ovariotomy, the temperature went up to 111°, two degrees higher than it was immediately before death. Speaking of post-mortem movements, he referred to the custom at Vienna of placing a bell-rope in the hand of the corpse; the bell had only been rung once, and that was after death from Asiatic cholera. In catalepsy some amount of respiration went on, and the limb, if put in an extraordinary position, remained so; he found that a blow upon the spine brought these patients round. In deaths from lightning, he was under the impression that the electric fluid usually made a mark of entrance and of exit, and that the blood remained fluid. —*Lancet*, Dec. 15, 1888.

Infanticide in China.

The *Sei-I-Kwai Medical Journal*, of Tokyo, Japan, publishes in its September issue the following account of infanticide in China, which shows a lamentable prevalence of the crime: In a series of papers on infanticide in China, read at a meeting of the North China Branch of the Royal Asiatic Society in Shanghai on May 14, 1885, Dr. Edkins and Mr. Balfour both allude to a bullock cart which perambulates the city, collecting the corpses of infants for burial. It is extremely difficult to obtain accurate information upon any subject in China, and the particulars given concerning the details of this charity vary with each informant, but the following may be taken as a fairly correct account of the matter: Except in the more respectable families with some money to spare, it is considered useless extravagance to bury with any formalities a child under ten years of age, and going lower in the scale we find that infants of the poor are often simply thrown out into the fields or canals, where they are at the mercy of dogs, instead of being properly interred. To meet this distressing state of things, at any rate inside Peking, there are two carts in connection with the Imperial Foundling Hospital, which make daily rounds to collect the little corpses for burial in ground set aside for that purpose. Each cart has its district, one for the East city and one for the West, which it visits daily. Here it may be well to mention that some informants state that there is only one cart actually, which visits different parts of the city in turn. The carts are each drawn by a bullock and driven by an old man—the object being that they should move slowly and reverently. They always take the right of way as being Imperial equipages, and everyone, even high officials, must yield the road to them—which most people are only too glad to do, especially in hot weather. They are the ordinary travelling carts with the cover, which in their case is black, and are known as "compassionate dry land ferry," being an allusion to the ferry "in which Kwan-yin carries souls to rest." Outside each gate are established stopping-places, generally in connection with a temple, where the bodies are brought by women to await the cart, which carries its pitiful freight to cemeteries outside the Southeast and Southwest corners of the city. These burial grounds are either Imperial property or the gift of the charitable. The person bringing a corpse to the Niu ch'e Fang pays 400 cash. The bodies are sewn up neatly in matting, or very occasionally enclosed in a rude coffin. They are not buried separately, but in a common grave. It occasionally happens that a cry reveals the fact that a little one is not dead, in which case it is taken to the Foundling Hospital, where its life hangs on a very slender thread, unless it is speedily adopted. The most significant fact in connection with the institution is that *no examination is made of the bodies*, a startling proof that whether infanticide does or does not exist to any great extent, the Government does not regard it as a matter of the slightest consequence. As for the quantities buried no statistics are obtainable, but the cart has been seen crammed full of these abortive attempts at increasing the population, even the rest at the back being piled high with the little packages.

Pseudo-scientific Humbuggery.

In a letter to *Science*, December 7, 1888, Charles F. Cox, of New York, says:

The more mysterious a thing is, the more do ignorant people think they know about it. The learned man alone recognizes the limitations of his knowledge. On our maps the thoroughly explored regions have strict boundaries: only the *terræ incognitæ* shade off into infinity.

Now, of all the uncertain subjects at present passing under scientific scrutiny, the etiology of infectious and contagious diseases is probably the most occult; but, for this very reason, it offers irresistible attraction to all sorts of rash theorizers. At the same time, the excitement occasioned by the visit of an awful plague, like yellow fever, discloses a ready soil of credulity for the reception of every wild dogma, and starts into life the germs of superstition everywhere lying dormant in men's mental substratum.

If you care to see how charlatans take advantage of such a concatenation of circumstances, you have only to walk through upper Broadway, and drop in at the headquarters of a certain "microbe-killer," which you will have no difficulty in finding. Even if the proprietor's explanation of his wonderful invention does not strike you as being altogether lucid and ingenuous, you will surely be impressed with his apparent knowledge of and faith in human nature, as shown in the certainty with which he reckons upon a paying market for his extraordinary nostrum. This is evinced also by the fact of his occupying a conspicuous place of business, for which I suppose he has paid a good rent, and, perhaps even more indisputably, by his having risked the expense of a two-column advertisement in one of the daily papers a few weeks ago. The astonishing effrontery of that advertisement is manifested, not only in the ingenious nonsense put forth as a history of the alleged discovery, but also in the impressive pictures with which the highly imaginative article is adorned. These profess to be likenesses of the "deadly microbes" for which the infallible "killer" has been providentially provided. Of course, there is not a microbe among them. They are, however, with one exception, rude reproductions of photographs of diatom valves. The exception is a representation of a part of the tracheal system of a butterfly or moth. . . .

It is the greatest shame of these impositions under the guise of science that professional men of some reputation at times lend them their countenance and aid. And, even when the thing recommended is not itself fraudulent, the mode of indorsing it often becomes so. An example of this came under my notice not long ago, when, in looking over a newspaper, my eye was caught by the word "microscopical" occurring in a rather prominent advertisement of a certain soap, and upon examination I found that a gentleman of scientific claims had undertaken to give a certificate to the merits of the article advertised. Now, soap seems to be a thing about which comparatively little can be said from a sanitary point of view, except that a free use of it is desirable. But in the testimonial of which I am speaking there was manifested a wide-awake disposition to make the most of the passing public interest in infection and contagion. With remarkably lame logic, the scientific attorney of the manufacturer declared, in substance, that, having submitted the soap to microscopical examination, and having found it free from disease-germs, he was prepared to recommend it for its detergent qualities.

While we do not wonder to see a Wiggins rush forward, upon the very slightest excuse, as he did but lately, with a sixteenth-century astrological theory of yellow fever, we cannot but feel both astonishment and mortification when a good chemist publicly dispenses bad microscopy, or an eminent physicist plunges headlong into hygiene and therapeutics, as one did the other day. A man may have almost superhuman insight as to the laws of electricity and yet be as ignorant as the rest of us about the how and why of a bacillus or a spirillum. It was not very strange that a gentleman hitherto absorbed in physics and mechanics should prove to be uninformed as to the unsuccessful endeavors that had been made to isolate and identify the microbe of yellow fever, for he had come across-lots into a scientific region of which the literature and even the language was unfamiliar to him. For the same reason, how was he to know that what would kill an ant would not necessarily kill a bacterium or a vibrio?

The trouble is, that a large part of the people who are most ready to discuss the new phase of biological science have not the faintest idea of what a microbe is. Most of them seem to fancy that merely a new name has been invented for what used to be called a spore or a germ; and of course everyone knows what a germ is, for he has only to look at the seed of any well-known plant! This seems to be the difficulty with a famous military commander

who has recently taken up the weapon more powerful than the sword, and, by means of it, given to the world, through one of our magazines, his *a priori* exposition of the mode of origin and spread of epidemic diseases. He may fairly claim experience in keeping yellow fever out of a community, but, after reading his article, we may well doubt whether he really has much information as to how it gets in.

In short, pseudo-scientific humbuggery is very prevalent just now; but I suppose we may console ourselves by regarding it as a popular tribute to the worth of true science, since we are told that "hypocrisy is a sort of homage that vice pays to virtue."

Medical Missions in the East.

In an interesting article in the *Sunday School Times*, Jan. 12, 1889, Dr. George E. Post, of Beirût, Syria, says:

A few years ago the illustrious Abd-el-Kadir, the Algerine hero who saved thousands of Christian lives in Damascus at the time of the massacres, was taken ill. I was sent for to attend him, and succeeded, by a surgical operation, in relieving his sufferings and prolonging his life. Since that time his eldest son has been under my care, and thus an influence secured in one of the most powerful families of the East. I shall never forget the evening when the success of the operation gave relief to the obstruction under which he was sinking. His large harem was assembled under the windows of his suburban home near Damascus. It was an early evening hour, and, by the faint moonlight, their sheeted forms could be seen, like ghosts, among the trees of the garden. When the news of the relief experienced by the aged prince was sent down to them, they set up a shout of triumph and thanksgiving which echoed far away among the chalk cliffs of the Abana valley, and then crowded around the door to catch up and transmit each item of encouragement, while the noble sufferer threw his arms around my neck, and kissed both cheeks, in token of his gratitude.

It would be easy to prolong this list by adding the names of governors and mayors, and military commandants, and even the ecclesiastical dignitaries of the Christian and Jewish and Mohammedan and Druze and Mutawâli sects; kadis, muftis, zaptiehs, sheiks, pachas, rabbis, bishops, patriarchs. To name them all would possibly seem like egotism, and would only confirm the fact insisted on at the outset, that the medical man has access to those whom no other can reach.

Let it not, however, for a moment be supposed that the writer, or any missionary, attaches too much importance to the high station of some of his patients. Even as the result of medical evangelism, "not many wise, not many noble, not many mighty," are called. It is from the weak ones, the lowly classes, that God constructs his kingdom. But here the same principle obtains. The medical man can enter *by invitation* doors that would be slammed in the face of any other missionary. Nay, the candidates for healing come from all parts. I have just discharged a patient from the hospital, who walked from Mosul to receive treatment. Forty days' journey on foot did not discourage him from seeking and finding relief. They come from Tartary and the Sahara, from Arabia and Asia Minor, from Palmyra and Bagdad. On any clinic day the dispensary ministers to people of a dozen nationalities and creeds; and at the hospital service these patients hear the gospel, which no other influence could bring to bear on them. The power which the medical man has over the great ones of the earth gives him influence over the feeble. His reputation as the counselor of princes, the guest of Pharisees, the healer of kings, the friend of priests and bishops, is the substratum on which he builds his influence with the outcasts and the oppressed. Picturesque as is medical work among the lordly in their castles, the power of the healing art is in the cabins of the poor, in the halls of the dispensaries, and the wards of the hospitals. A commodore of the United States Navy, who did not believe in missions, once told the writer that there was one sight which impressed him as the most Christ-like he had ever witnessed. It was a medical missionary, in his dispensary in Singapore, toiling all the morning long with those wretched outcasts, in the stifling air of a pest-stricken city, and all for the love of Christ. Against such an exhibition of unselfish benevolence no cavil can be brought. And the same effect is produced on the native mind. Such a service, so above all that their religions can match, so without precedent or basis in their own experience, is from another world. They are accustomed to see Europeans and Americans as conquerors, as seekers after commercial gain, as travelers searching for knowledge or pleasure, but here are persons who offer them a living demonstration of the Golden Rule, and although using science and art, yet using them under the inspiration of a purpose from on high.

Phenacetin.

Pesce has communicated to the Royal Academy of Turin some clinical observations upon phenacetin. It effects pronounced and lasting fall of temperature and has a favorable influence upon the general condition of the patient. This fall and the subsequent rise of temperature occur nearly always slowly and gradually. Seven and a half grains usually produces a fall of two or three degrees C.; this dose should be given once. The fall of temperature usually occasions no disagreeable or dangerous symptoms, apart from perspiration, which is never copious.

Phenacetin also possesses a powerful antirheumatic action; it suppresses the fever and the pains in the joints, lessens the feeling of oppression, and makes the movements of the joints freer. It also exerts a favorable influence upon apyretic rheumatism, but upon the disease process itself it has no effect. It is of service as an analgesic in neuralgia, headache, migraine, and conditions of irritation of the sensory nerves. As a rule, seven and a half grains are sufficient to cause disappearance of the pain; where it is necessary this dose can be repeated after two or three hours. In disturbances arising from compression or from anatomical or functional lesions of the nerves, such as neuritis, fifteen and a half grains must be employed, and repeated if necessary.—*Deutsche med. Wochenschrift*, Dec. 6, 1888.

Is Instrumental Delivery a Cause of Idiocy?

Drs. Winkler and Bollaan have written a paper in a Dutch medical journal on "The Forceps as a Cause of Idiocy." They mention a case of bilateral, almost symmetrical, damage to the cortex of the brain, found in an idiot. The boy had been born with the aid of forceps. Only part of the vertex could be examined. There were no marks of the forceps, yet there were strong reasons for belief that the injury was caused by them. In another case there was still more ground for the opinion that injury had been caused by forceps. In this child, who was an idiot from birth, there were marks of the forceps on both sides of the skull corresponding almost exactly to the damage done to the brain. This coincidence was too remarkable to be accidental. Drs. Winkler and Bollaan performed necropsies on ten idiots, and examined twenty-five living idiots, of whom six had bilateral depressions in the skull. Another case was that of a woman born with the aid of forceps, an inmate of the Utrecht Asylum for four years. She was very short, being only 1.27 metres high, and small in proportion. She could make all movements, isolated movements being difficult to her. There were but two words which she could say, and she never gave any sign of understanding what was said to her. She died at the age of sixty, and at the necropsy the brain was found to be very small, weighing only 742 grammes (31½ oz.). All the organs at the base of the brain, the optic nerves, olfactory nerves, etc., were found to be very small. Deep depressions were found on either side of the sagittal suture, the right side being the more indented. The depth of the depression was two millimetres, and its greatest breadth twelve millimetres. The brain was much atrophied. The authors believe that depressions of the skull caused by instrumental delivery, even when no fracture occurs, tend to damage the cortical substance of the brain, and that this leads to general atrophy of the hemispheres, thus producing idiocy. They are disposed to think that the use of forceps is much more frequently the origin of idiocy than is generally supposed.—*Lancet*, Jan. 5, 1889.

A Doctor's Perilous Experience.

On the night of Wednesday, January 9, 1889, the suspension bridge just below the Falls of Niagara was blown away in a terrific windstorm. It is not known that any one was upon it at the time; but the last man to cross it before its fall was a physician. Dr. J. M. Hodge, of Niagara Falls, N. Y., started across the bridge about midnight on his return from visiting a patient on the Canadian side. Believing the bridge to be perfectly safe, he started without any fear. When but a short distance from the Canadian side he realized that something was wrong. As he neared the centre he was obliged to get down on his hands and knees and creep along. At times he did not dare to move. The bridge, he says, rocked like a boat in a heavy sea, and at times it seemed to tip up almost on its very edge. Not for an instant did the Doctor dare let go the iron railing, but he found several places where it was bent so that he was obliged to feel his way around.

There was no light on the bridge, the night was very dark, and, to add still further to his discomfiture, great volumes of spray from the Falls swept over the

bridge, drenching him to the skin. The wind actually tore open the struggling physician's overcoat. At that hour evidently the shore guys were broken, for the Doctor could hear them flapping, and the bridge must have first begun to give way about that time.

Electricity for Executions.

The correspondent of the Philadelphia *Ledger* writes from New York, under date of Jan. 6, that it is not unlikely that, at the present session of the Legislature, the law which went into effect the first day of the year, providing for the execution of murderers by electricity, will be repealed, or the time extended for its going into effect. It is not altogether sure, he says, that executions by electricity can be made without pain or mutilation. Electricians are divided on the subject, and the majority seem to be opposed to the law. It is noticeable that every electrical journal opposes the electrical method of execution as inexpedient and inhuman, and in a recent address Professor Brackett, of Princeton College, spoke of execution by electricity as an outrageous thing and the degrading of a noble agent to an ignoble use.

"The American College of Health and Vitapathic Institute."

The great need of effective State Licensing Boards is made apparent to everyone on reading such items as the following, which is taken from the Philadelphia *Ledger*, Jan. 25, 1889: "A man recently applied for registration as a practising physician to the Secretary of the Board of Health in Baltimore, exhibiting a document purporting to be a diploma issued by 'The American College of Health and Vitapathic Institute' of Cincinnati, J. B. Campbell, President (which, it is said, turns out doctors in five weeks). The caller was refused registration on his diploma, but he afterward showed a letter from J. B. Campbell, which said: 'Vitapathic Minister Physicians need not register; Health Boards have nothing to do with us, as we never let our patients die, but if they do, or will die, call in an M.D. in time.' The Secretary informed him that the laws of Maryland in regard to the practice of medicine are so loose, that almost any one can practice, but in the event of a patient dying the coroner would order an autopsy, and should any malpractice be revealed, the practitioner would be summoned before the Grand Jury."

A Three Thousand Dollar Prize Offered.

A committee of the Caspian Sea (Russia) fishing firms offers a prize of 5,000 roubles (nearly $3000 nominal) for the best pamphlet in English, French, German, Russian, or Latin on the subject of the nature of the poison which is formed in raw salted fish. The pamphlet should explain the physical and chemical nature of the poison; its effect (as demonstrated by experiments on animals) on the heart, the circulation of the blood, the digestive organs, and the nervous system; the time required for the absorption of the poison into the digestive organs; the methods by which contaminated fish may be distinguished from sound; the indication of means by which the development of the toxic elements can be arrested; and the indication of the antidotes and medical assistance required in cases of poisoning. Information may be had and answers should be addressed to the "Imperial Ministry of Domains, St. Petersburg."—*Chemist and Druggist*, Jan. 5, 1889.

The Hunt Memorial Hospital.

Dr. J. H. Hunt, of Port Jervis, N. Y., has erected a hospital in that town, in memory of his father, the late Dr. Isaac S. Hunt. The building, which is a three-story brick structure, contains a ward in which are ten beds, eight rooms for private patients, three offices, an operating room, a hall, a dining-room, and a kitchen. The hospital is intended for the reception of injured employés of the Erie Railroad and for the personal patients of Dr. Hunt. The sanitary arrangements and equipments of the building are all that could be desired for the comfort of patients.—*N. Y. Med. Journal*, Jan. 19, 1889.

The Philadelphia Hospital.

A bill has been introduced into the City Councils of Philadelphia providing for the setting aside of a certain portion of the House of Correction property for the erection of buildings to be occupied by the indigent poor of Philadelphia. This bill, if passed, will result in the very desirable separation of the Philadelphia Hospital and the Blockley Almshouse, the former of which is much over-crowded and should, moreover, be relieved from the stigma which intimate association with an almshouse imposes upon it.

NEWS.

—Small-pox is said to be epidemic at Azalia, Dundee and Milan, Michigan.

—It is reported that there are twenty-one cases of small-pox in Oberlin, Kansas.

—Scarlet fever and diphtheria are reported to be prevalent at College Point, New York.

—Eighteen cases of small-pox are reported from Milan township, Monroe county, Michigan.

—The Lehigh Valley Medical Association held a Winter Conversational Meeting at the Hotel Allen, Allentown, January 31, 1889.

—Dr. William Osler gave the first of three lectures on Cerebral Localization at the Orthopædic Hospital in Philadelphia, Jan. 19, and the second, Jan. 23.

—Dr. E. B. Brant, a well-known physician of Mechanicsburg, died Jan. 19, at the age of 60 years. He was graduated from Jefferson Medical College in 1855.

—The proprietors of the *Lancet* have set apart $1,500 to be used for the pecuniary assistance of medical men, and of their widows, orphans, or dependent relatives.

—Prof. L. B. How will deliver the next course of lectures on Anatomy at the Medical School of Maine, in place of Prof. Gerrish, who is in California recruiting his health.

—The clinical service at Vienna is said to be seriously embarrassed by the great number of students, native and foreign, and by the enormous increase of patients for consultation.

—At the festival *de Noël* Mme. Carnot sent to the Director of Public Assistance, of Paris, one thousand francs for the children of the hospital Trousseau, and the hospital for Sick Children.

—The hospital collections in New York, up to Jan. 16, amounted to $38,000. The Childs' Nursery and Hospital is said by the *Med. Record*, Jan. 19, to have realized $19,000 from the Charity Ball.

—Passed Assistant Surgeon W. G. G. Willson was found dead on the U. S. Receiving Ship St. Louis, at League Island, Philadelphia, Jan. 23. He is supposed to have died from the effects of a dose of chloral, which he had taken for insomnia.

—The *Lancet*, Jan. 19, announces that an International Congress of Physiology will be held at Basle, Sept. 10, 1889. The Congress will also embrace the subjects of anatomy, histology, physics, chemistry, experimental pathology and pharmacology.

HUMOR.

Feeling His Oats.—George—"I say, Gus, what's happened? You strut along the street as if you owned the whole city. Fallen heir to a fortune?" Gus—"No, but I've been dodging my tailor for eighteen months, and to-day I've got the money in my pocket to pay him."

The Editor of a Religious Paper in Michigan solemnly promised his subscribers that he would sample all the patent medicines offered to him by advertisers before he would insert the notices. This was four years ago. He is now an inmate of an inebriate asylum.—*Burlington Free Press.*

More Protection Wanted.—(The effect of an editorial in a contemporary)—Workingman—"See here, I want protection." Great Statesman—"Certainly, certainly; you shall have it. What's the matter?" "Well, sir, some of these 'ere foreign doctors know so much that they keep folks alive too long. I want foreign doctors kept out o' this country. I'm a grave digger."—*Philadelphia Record* (*Dem.*).

Better than Nothing.—Mr. Dickinson Compton says: A very handsome man, of large form, fell off the railway platform at Camp Hill, falling under the train, and had one thigh and the leg of the other below the knee completely smashed. He was brought to the General Hospital and both limbs were at once amputated. The patient gave me much anxiety; but he continued to live, the wounds healing well. I found he was engaged to be married to a very nice, respectable young woman, whom I found one evening sitting by his side. I said I thought she should think very seriously about her engagement, hinting that I thought it had better be broken off; but she most naïvely said: "Oh! sir, I am quite content to take the rest of him."—*Guy's Hospital Reports.*

OBITUARY.

JOHN M. JUNKIN, M.D.

Dr. John M. Junkin, of Easton, Pa., died of apoplexy Jan. 18, while in the office of the Adams Express Company. He was 67 years old and was well known throughout Eastern Pennsylvania. He was graduated from Jefferson Medical College in 1845. His father was President Junkin, formerly of Lafayette College. Dr. Junkin served during the war as surgeon in the Ninth, and later in the Fourth, Pennsylvania Cavalry. He recently returned to Easton, his former home, from Bucks county.

The date given is that to which each subscription is paid.

If it bears the letter "C," and a number, this signifies that you are a subscriber to the COMPENDIUM and that it is paid for to, and including, the number given (No. 58 is the last number for 1889).

ATTENTION to this matter, and prompt remittance of the subscription price (to January, 1890), will greatly oblige the Publisher.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co, Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Clinical Lecture.[1]

CASE I: CEREBRAL SYPHILIS; CASE II: ASTHMA CAUSED BY A FOREIGN BODY.

BY J. M. DA COSTA, M.D., LL.D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE IN JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

Cerebral Syphilis.

Gentlemen: The patient now before you (a man, about 40 years of age) you saw at our last meeting, when I read you his clinical history. Briefly, it was this: He had had frequently recurring attacks of convulsions, limited to the left arm, occasionally the right arm also would participate in the spasmodic movements, though not to the same degree. He never had general convulsions, and the lower extremities were never involved. These attacks were attended by vertigo and confusion of ideas. He had constant tinnitus aurium, and in addition to the ordinary sounds of escaping steam and chiming bells, he heard sounds resembling a band of music and even human voices; all these being increased during and after the attacks, which came on several times a day before his admission. We ascertained that he had no paralysis of the extremities, and sensation is well preserved. He does not suffer with headache. He does not lose consciousness during the attack, and does not vomit. There is marked diminution of the power of hearing in both ears, but he is more deaf on the left side than on the right. His eyes were examined, and, beyond some error of refraction, nothing abnormal was found. There is no heart-lesion; and no albumin was detected in the urine.

In seeking an explanation of these symptoms, which I have briefly detailed to you, two possibilities are presented: in the first place, is this a tumor of the brain? In favor of this view, we have the convulsions limited to the muscles of the left arm. Limited convulsive movements point to an irritative cortical lesion, such as a tumor would

[1] Delivered at the Pennsylvania Hospital, December 1, 1888.

cause. The vertigo aggravated during the attacks, but occurred also at other times, is one of the symptoms of brain tumor. Then the deafness, unconnected with ear disease, and therefore central, might be caused by pressure of a new growth upon the auditory nerve. Why do we have the ear-affection upon the same side as that of the arm affected by convulsions? Because the law is that while a destructive lesion will cause paralysis upon the opposite side of the body, an irritative cortical lesion causes spasm upon the same side as that upon which it exists. But why does the right arm participate at times? I can only conclude that its movements are reflex. Brown-Séquard would have no difficulty in thus explaining it, because he believes that most of the phenomena of brain disease are due to the reflex action of one part of the brain upon another.

In spite of the reasons given for assuming that the symptoms are due to a cerebral tumor, I must decide against this view for several reasons. In the first place, the symptoms just mentioned are not sufficiently persistent. The symptoms of brain tumor are progressive, and constant. Moreover, one very prominent feature of cases of brain-tumor is entirely absent; he has no headache. He has no vomiting. Finally, the ophthalmoscopic examination does not show the choked disc which is so generally found in cerebral tumor. The report is that the eye-ground is quite normal, his ametropia being simply an ordinary fault of refraction which can be remedied by appropriate glasses.

The case not being one of tumor, my diagnosis would be disease of the brain or of its vessels, due to syphilitic infection: cerebral syphilis. His marked improvement since his admission a fortnight ago, while he has been taking a drachm of potassium iodide daily, would favor this view of the case. He has also had some bromide at night. He is doing well and has no vertigo at present, although he still has ringing in his ears. Standing or walking with his eyes closed, he gives no evidence of incoördination. He has not had a convulsive seizure since he was before you last; the treatment will be continued for the present.

[Feb. 1. The patient is still in the Hospital, but has very greatly improved.]

Asthma Caused by a Foreign Body.

The next case is peculiar and possibly unique in character. It is also one of convulsions, and therefore very properly discussed in connection with the preceding case, although it presents special features which are of more interest than the brain symptoms.

This boy, white, sixteen years of age, was admitted November 26, having been brought to the Hospital by the Police Patrol, who found him lying on the street in a fit, which was clearly epileptic in character. We learned that this boy received an injury by being struck with a brick on the left side of his head, about six years ago. He tells us that about two years after he was struck upon his head, convulsions came on. In spite of treatment, the convulsions persisted, and they became so frequent that he had to seek surgical advice. Two years ago, at the Hospital of the University of Pennsylvania, Dr. John Ashhurst trephined his skull at a point which can be still recognized; it is above and on a line with the left ear, at about the centre of the parietal bone, where a depression can still be felt. He says that, at first, no relief was obtained from the operation, but that lately there has been improvement; the convulsions now occur about once in three weeks; he had them sometimes twice a day before the operation. It is a fair inference that he was benefited by the operation, although he says that for about eighteen months there was no benefit, yet since that time he has markedly improved.

The special point to which I wish to ask your attention is this: On the 26th of November, the day he was brought into the Hospital, he had a fit or attack of convulsions upon the street, and became senseless. As he was recovering from the attack, he experienced great difficulty in breathing. When he came to the Hospital he was conscious, but was suffering intensely with difficulty in breathing. His respiration was labored and noisy, like that of asthma, and the expression of his face showed that he was laboring under great respiratory distress. He was seen by one of my colleagues, who happened to be present when he was admitted, and who kindly went into the ward and prescribed for the patient. Partly from his account and partly from that of the Resident Physician—for I did not see the patient until half an hour later, when he was somewhat relieved—we learn that the breathing was noisy, the inspiration weak, and the expiratory sound was prolonged. It was especially upon the left side that the expiratory sound was asthmatic; in fact, he presented the symptoms usually seen in a case of asthma. He was distressed and

struggling for air; respiration labored, expiration very distinct and noisy. The heart rate was accelerated, but presented no signs of organic disease. He was ordered tincture of belladonna in ten drop doses with a little ammonia and subsequently ergot; and his chest was dry cupped. The prescriptions, all of which had for their line of thought the relief of spasm, were followed by great benefit. The breathing became better and easier, and he went to sleep. It looked as if all these antispasmodics had accomplished their work, and that the attack had passed away, when, about twelve hours after admission, during the night, he had a severe attack of dyspnœa with coughing, lasting about fifteen minutes, and, while the physician had gone for the laryngoscope, up came the piece of apple which I now show you. It is a little shrunken from the action of the alcohol in which it was placed for preservation, but it is still a piece of considerable size, longer than broad and irregular in shape. (It was about ⅞ of an inch in greatest length and about ½ by ⅝ in cross section.)

We then got this strange history that when the epileptic fit seized him he was eating an apple. During the convulsion this piece slipped from his mouth into his windpipe, and owing to the insensibility during the attack it was drawn into the trachea and lodged below the bifurcation, obstructing the left bronchus rather more than the right, and thus explaining the difficulty in breathing. He subsequently had a severe attack of dyspnœa in the middle of the night, in which he nearly died, and which was terminated by the expulsion of the foreign body. He has since had no signs of asthma; but was allowed to continue taking bromides, simply with the view of preventing the recurrence of the epileptic fits.

There are several points of clinical interest in this case. One of these is the way in which the symptoms of spasmodic asthma were closely simulated by the presence of this foreign body in the trachea lying at its bifurcation into the bronchi, which caused intense distress and labored respiration. But what was curious, he had also the physical signs of asthma; intense dyspnœa, noisy breathing, prolonged expiration, and weak inspiration; the percussion note was clear. There were no rales in the finer tubes; but, with this exception, he had all the symptoms which we would expect to find in a case of asthma.

Now what were these signs due to? A condition of spasm in the bronchial tubes. Therefore, if I say that it is like a case of spasmodic asthma, I may go further and state that this foreign body provoked an attack of asthma. There is almost identity of pathological condition.

Again, as bearing upon this view of the case, look at the results of treatment! They were most remarkable, and I might say most decisive. If it had not been for our getting the piece of apple, it would never have been supposed that a foreign body in the air-passages had caused the symptoms.

From the free use of belladonna and free cupping, there was most evident relief; the spasm, which had been evoked by this foreign body, yielded, and the patient breathed more easily and even went to sleep. Therefore the means employed largely removed the irritation, notwithstanding the cause remained.

Lastly, I may call your attention to this fact, that this foreign body had passed beyond the trachea, because if it had lodged in the wind-pipe, it would have given rise to much greater difficulty in breathing, and would have impaired his voice. As you heard in his history, his voice was distinct, but was feeble on account of his respiratory distress. So that in the violent convulsion which came on while he was eating the apple, this piece was inspired into the larynx, which, owing to the insensibility produced by the convulsive attack, allowed it to pass into the trachea, and into the left bronchus just at the bifurcation, where it caused irritation and set up spasmodic asthma, due to a foreign body.

At present his breathing is easy and natural. Upon auscultation, the inspiratory sounds are well marked on both the right and left side; nor is the expiration either prolonged or abnormal in character. The same condition is found posteriorly as anteriorly. The breath-sounds are not quite so strong at the lower part of the left lung anteriorly as at the corresponding part of the right lung. The percussion note is clear. The heart, which was feeble, has regained its tone. There is nothing abnormal.

His temperature is rather low. On admission it was 98.6° (F.), and it has since declined. This morning it is 96.4°; his usual evening temperature is 97.8°. Possibly the morning temperature may be lower on account of being taken after his ablutions, but the evening temperature is also low; since admission it has not exceeded 98°.

He has been taking twenty grains of

potassium bromide three times a day; but considering that he has this tendency to coldness, we will give him aromatic spirits of ammonia, half a drachm (f℥ ss) three or four times daily. He shall also take exercise in the open air, and he shall have a nourishing but not too stimulating diet.

COMMUNICATIONS.

THREE REMARKABLE CASES OF REFLEX NEUROSES DUE TO EYE-STRAIN.

BY GEORGE M. GOULD, M.D.,
PHILADELPHIA.

There are some physicians who are at once seized with an acute attack of mental strabismus when they are told stories of peripheral irritation inducing functional disturbances, such as the following cases. The *superior oblique*, not the *internal rectus*, is the muscle affected. They distrust the Greeks even when bearing therapeutic gifts, and smile incredulously. For this reason I have hesitated to publish the notes of the following cases; but since the facts are well-known to several reputable physicians and may be substantiated at any time, and since, moreover, I believe all these cases range themselves under a common law that explains their apparent illogicality and makes them intelligible, I conclude it best to make them known to others.

Case I.—Chorea of Several Years' Duration Relieved at once by Correction of Ametropia.—Susie H., aged 14 years, came to me, Nov. 7, 1888, with the following history and complaints: Twitching of the right hand and foot was first noticed two or three years ago, coming on without noticeable cause. Since then up to this date she has been treated for chorea at one of our best Hospitals for Nervous Diseases. She gets somewhat better during summer, but when school again begins, she gets worse. Latterly, and just previous to coming to me, she had been having frontal headaches every day with attacks of giddiness or dizziness. Her mother and sister complain of her violent outbursts of temper. Sometimes, even in street-cars, and upon the slightest provocation she will burst out crying, or jump up and down and scream. The chorea, however, was the chief cause of complaint, and this seems to have continued during sleep, her sister being frequently disturbed or awakened by the jerking. The right shoe was worn out much sooner than the left, and as the child sat before me the motions of the hand and foot were continuous and painful to see. Menstruation began three months ago, but certainly had not made the chorea any better. In the history of the case I particularly noted that there had never been any blepharospasm or tic of the face. The child was physically a robust, well-built young woman, otherwise in excellent health, without a sign of hysteria, and whose parents were likewise of non-neurotic healthy temperament. When she came to me she was taking twelve drops of Fowler's solution three times a day, which had been ordered by the physicians of the hospital. The arsenic had no evident effect upon the disease and the order was to increase the dose until certain well-known symptoms were noted, or until she became sick from the effects. Under a mydriatic I ascertained her refractive error to be alike in both eyes, and corrected it by the following combination of lenses: Sph. + 1.00 D. = Cyl. + 0.75 D. Ax. 90°. Spectacles were prescribed and the arsenic treatment wholly and suddenly suspended. Instead of the choreic symptoms being thereby increased, her sister a week later told me that she was no longer troubled by the child's movements at night. In fact the involuntary movements of both foot and hand slowly disappeared, so that in three weeks after the application of glasses none were noticeable. The headaches, etc., have disappeared and the disposition changed for the better. So far as the chorea is concerned, it does not exist to-day.

Case II.—Flatulent Dyspepsia of 20 Years' Standing Cured by the Application of Spectacles.—On Nov. 11, 1888, Mrs. E. G., aged 44, was kindly recommended to me by her physician, Dr. O. P. Rex, who had after oft-repeated advice, finally got her to consult an oculist. Her complaint was of certain ocular and cerebral troubles, asthenopia, difficulty in near work, etc. She had had headaches for most of her life. She did not complain to me of her gastric troubles, naturally thinking these had no connection with an oculist's work. But inquiry soon elicited the information that her flatulent dyspepsia ("wind-colic," as she called it) was her greatest trouble, and that her life for at least 20 years had thereby been rendered most wretched. At once upon entering I noticed the constant eructations which were very unpleasant and continuous. The knowledge of the fact of the disgust excited in others, together with the disease itself had rendered her very

despondent and subject to melancholia. There were evident lassitude, prostration, a look of suffering in the countenance. She complained of a constant "load upon her stomach," and of loss of appetite, which last had been a great cause of weakness and debility. In the past 20 years she had had the services of several excellent physicians and had taken a great deal of many different medicines, all without relief. The least conversation with the woman showed the complete absence of any hysterical element. She had healthy parents, and had been a plucky, hard-working woman all her life, enduring and fighting her affliction with a heroism that few would under like circumstances have shown.

I was put upon the track of my diagnosis by the following fact: When I put her in position to examine her eyes with the ophthalmoscope, the unpleasant eructations were as usual constantly taking place; but, upon throwing the light from the mirror full into the eye, such an instantaneous and frightful paroxysmal attack took place that I hastily ran for a vessel, convinced that violent emesis was taking place. But it was only flatus. A repetition of the attempt had the same result, and I had to give it up; but the thought at once came to me that I now had to do with a reflex neurosis. To be brief: I found her refractive error indicated by the following combination: For Distance:— R., Sph. — 0.25 D., = Cyl. + 0.75 D. Ax. 110°; L., Sph. — 0.25 D., = Cyl. + 1.00 D. Ax. 70°. The presbyopic correction was Sph. + 1.50 D. added to the above. It was highly interesting to notice that the application of the distant glasses, in the trial-frame, as effectually quieted the gastric volcano as the ophthalmoscopic mirror had previously aroused it. So long as the lenses were in place, no eructations took place; the effect was so pleasant she was unwilling to have them removed, but when this finally became necessary the eructations instantly recommenced. On November 24, having procured and worn the prescribed glasses *ad interim*, my patient returned, saying she had had none of her old symptoms during the time she had worn the glasses. I remarked a look of zest and happiness in her face in marked contrast to that of her first visit. Her appetite had greatly improved, the "load" had disappeared from her stomach; she had had no "belching"; the headache and the lassitude had disappeared; she had been heard to sing at her work, and all her friends remarked the change in her appearance. She said she could not leave the glasses off a minute without trouble. Without apprising her, I fixed her gaze upon small distant letters, so to put the accommodation to a tension, and, while thus looking, I suddenly raised the glasses away from her face, and like a flash the eructations broke forth. I dropped the glasses, and they disappeared. Here was evidently as pure an example of neurotic reflex as one could wish. The improvement in health and the complete absence of gastric, cerebral, and psychological symptoms continues up to the present time.

Case III. — Cardiac Palpitation, etc., relieved by Correction of Astigmatism.—I am indebted for the following notes to the courtesy of Dr. A. P. Brubaker, of Philadelphia, and Dr. Lewis H. Taylor, of Wilkesbarre, Pa. The patient was referred to me by Dr. Brubaker, but could not stop in Philadelphia sufficiently long to undergo examination and treatment of the eyes, which were carried out by Dr. Taylor.

Mrs. J. N., aged 24, married, without children, had enjoyed good health until during the summer of 1887, when, following a great deal of reading at night, she was troubled with severe pain and burning sensations in the eyes. Shortly after this, she began noticing how rapidly her heart was beating, and this symptom increased until the heart's action numbered as high as 130 strokes a minute. Then began a decline in health, with loss of appetite, feeble digestion and nervousness. She soon lost something over 20 pounds in body-weight. When seen by Dr. Brubaker in the spring of 1888, the rapidity of the cardiac action was still as great as ever, and slight cardiac enlargement was noted. She was placed upon the tincture of aconite for several weeks, without deriving any benefit from it. I should have added that treatment by other physicians prior to consulting Dr. Brubaker had also proved ineffectual in relief of the palpitation. On June 12, 13, and 14 Dr. Taylor tested the refraction, etc., of her eyes under atropia, and prescribed, for constant use, the following glasses: R. Cyl.— 0.75 D. Ax. 180°, ⌒ Cyl. + 0.25 D. Ax. 90°; L. Cyl. — 0.75 D. Ax. 180°. Upon wearing the spectacles the rapid action of the heart began at once to subside, and within two or three months all the symptoms, ocular, cerebral and cardiac, had passed away, the heart's action had become entirely normal, the body had regained its entire loss of flesh, health, etc.

Remarks.—To understand these cases and bring them under a common law we may be helped by likening the nervous system to the switch-board of a great telegraph-office. With every plug properly in place, every wire ends so that its messages are shunted to the proper table and operator and the out-going answers correspond to the call made. This corresponds to the physiological condition of the body when response is rightly co-ordinated to stimulus; when an outflow of saliva follows the placing of a sapid substance upon the tongue, when the capillaries expand by friction, when motion, secretion, etc., are the correspondent consequences of stimulus. If a careless or ignorant hand misplace a key of the telegraph switch-board there is chaos in the office, the messages do not reach the proper instruments, and replies are sent to the wrong far-away stations. Reflex neuroses are precisely such results in the body: the return messages do not reach the point of irritation, but some non-irritated organ which must then vicariously suffer for the sins of another.

Those who reluctantly admit the possibility of reflex neuroses, say that they cannot take place unless intermediated by centers in topographical proximity. They would say, for example, that an irritational strain of the oculo-motor could not result in choreic discharges from the phrenic or pneumogastric or cardiac centers, because of the distance of the "jump" or transfer. But may it not be that distance has little or nothing to do with the matter? This is not a saltation of the electric spark across a blank or insulated space. The number of associate fibers between centers is of course proportional to the functional relations of their peripherally located co-related mechanisms: but no center is wholly disconnected from any other, though the fact may not be anatomically demonstrated. The brain is certainly an organic unity and this is only possible by the means of myriads of commissural fibers proceeding almost everywhither and binding all ganglia together directly or indirectly. It is well established that chorea of the extremities may be caused by phimosis or other genital derangement, by a carious or impacted tooth, etc., etc., and yet the Rolandic centers are far-removed from those of the other organs. In place of topographical proximity, may there not be another law having a much more dominant power, that is, the law, or a corollary of the law, of the conservation of energy? Every irritational stimulus that from a peripheral organ proceeds inward may be viewed primarily in its dynamic aspect: it is force, and its function is to bring about another discharge of force whose nature and outgoing should correspond to the want indicated by the stimulus. If it is so correspondent, it is physiological; if it is not so, it is pathological, it is a reflex neurosis. But again this derouted discharge is also subject to the law that it must follow along the line of least resistance, and in accordance with this, its outlet will lead to those muscles and functions most easily moved. In irritational choreas the hand or foot or other small muscles are the most frequently set in motion. May it not be that sometimes when these channels become too small to drain off the overflow, other and greater centers are inundated, and that chorea thereby may even pass over into epilepsy? When slight irritational stimuli do not find such outlets, a general irritability and motility give vent and relief: a man with the toothache will walk the floor, a boy with "acute indigestion" will writhe and dance, a girl with eye-strain is restless and inattentive, etc. This overflow of unutilizable stimulus may according to peculiarities or habits become a tic, a strange habit of gesture, a chorea of the extremities, or, as it seems may have been true in my cases, what might analogically be called a chorea of the diaphragm, or a chorea of the cardiac muscle. But, whatever the explanation, such cases overlooked every day are doubtless more frequent than we suspect. This must be true when we think of the growing complexity of strain and nervous disease consequent upon our high-pressure civilization. Such derouta-tion and irregularity of outflow cannot help constituting in the future a prolific source of pathologic facts,—but a no less fertile source of brilliant therapeutics for the intuition and art sufficiently subtile and far-seeing to track out the hidden and distant *fons et origo mali*.

There can be no doubt that eye-strain is far above all others the one preponderant source of irritational neuroses. The incredulous smile at the hobby-riding specialist must give way to facts and the logic of facts. Here is a mechanism the most delicate, and moved by the slightest forces, of any in the organism; it is the most complexly constructed of all, its function the most important of all and the most used of all; its nuclear associations are the most wide, intimate and direct with all other centers, and every process of thought or

emotion is inextricably bound up with its functions and memories; language and intellect may be justly considered its products. And yet with all this, it must be remembered that within one or two centuries this wonderful mechanism is put to a strain for which it was never planned and to which in its evolution or history it has never been subjected. I allude, of course, to the persistent exercise at near range that is the necessary outcome of the art of printing, of schools, of commercialism, of urban life—in a word, of nineteenth century civilization. The natural eye is hyperopic and nature so forms it now. Ocular disease is growing as fast or faster than civilization. The sudden strain does not give time for the adaptation, even if one of these adaptations, myopia, be not a disease itself. If the naturally hyperopic eye, with nature's customary obstinacy persist in its hyperopia, and if in addition, corneal asymmetry (astigmatism) be superadded, even muscular insufficiency—then there can be but one result of the forced work at short range to which every servant of civilization is subjected. Unless every ametropic child have its ametropia corrected, either ocular disease, cerebral disease or reflex neurosis must ensue. This seems a certain result of the law of the conservation and equivalence of force. Pathology is but disordered, unregulated physics and physiology. In fact, the ophthalmic surgeon has not ridden his hobby half hard enough. He has been frightened by a sneer. If held "well in hand," his horse will not soon be winded. My own limited experience has convinced me that many general physicians are strangely obstinate in ignoring ocular strain, for years drugging their patients with bromides, iron and tonics, for cerebral or gastric derangements that disappear as if by magic when the eye-strain is relieved. Cases of tragic suffering due to such mistaken diagnoses are constantly turning up.

The cases I have described are all examples. Even where eye-strain is acknowledged to cause such neuroses, it is thought that several dioptres are necessary to set up the trouble. On the contrary, I have had cases where one-half and even one-fourth of one diopter is quite sufficient. Neither can such quantities be diagnosticated by the ophthalmoscope. To me the report from a hasty ophthalmoscopic examination that no eye-strain exists, is *per se* an evidence either of ignorance, or carelessness, or worse.

I have intimated that in my view the three cases described are essentially alike in cause and method of production: the chorea proper, the flatulent dyspepsia and the cardiac neurosis were all due to a peripheral irritation, eye-strain, that, derouted in its reflex course, returned somehow, directly or indirectly to other organs than to those concerned in the irritational stimulus. For other illustrations of this proceeding, see the excellent article of Professor Brubaker, *The Reflex Neuroses of Dental Pathology* in Lea's American System of Dentistry. There is no logical reason for limiting the term chorea to certain muscles, and a chorea of the diaphragm or of the heart muscle may prove as scientifically justified as one of the hand or foot.

As regards the details of the cases cited there is little to be objected to in the first case. It was a typical case of chorea, wholly uninfluenced by arsenic, and yielding quickly and completely when the irritational strain was removed. It may be said of the second case that too much is proved, because the 20 years of functional derangement must inevitably have set up organic changes that would not disappear in a day. I can only answer that the most brutal fact is worth more than the most beautiful theory; that the case is accurately reported; that a study of the symptoms, etc., seemed to show me that the gastric derangement was not due to imperfect secretion, was not chemical or organic, but was due to a spasmodic action of the diaphragm or of the muscular walls of the stomach. The fact, however, may bear other explanations, which I leave to others to give. As to the third case it may be true that the cardiac acceleration was due to a stoppage of the normal inhibition of its rhythm, and not to a positive increase of its innervation. In this case the force of the derouted reflex would find its own force neutralized in overcoming the cerebral inhibition.

—The *Ledger* says that Dr. Weisbach has been making careful measurements of the skulls of Beethoven and Schubert for the Vienna Anthropological Society. In his report he says that Schubert's skull, compared with measurements taken of 30 German-Austrian skulls, is slightly larger, longer and broader, but also somewhat flatter, than the average. Compared with Schubert's, Beethoven's face was altogether smaller, and much narrower between the cheek-bones, and especially about the lower jaw.

TECHNIQUE OF ABDOMINAL PALPATION.[1]

BY CHARLES P. NOBLE, M.D.,
PHILADELPHIA.

The following paper has been prepared as an addition to that on the "Value of External Examination in Obstetric Practice," which was presented to the Association September 26th, 1888, and published in the REPORTER, Oct. 20, p. 488. The request of some of the members is my excuse for bringing before you a brief and incomplete account of the technique of abdominal palpation—a subject which has been so ably presented to the profession by others, notably by Pinard. The subject of abdominal palpation as applied to the diagnosis of the presentation and position of the fœtus *in utero* only, will be considered.

Before proceeding to discuss the subject proper it will be well to recall certain physiological and mechanical facts which serve to render the results of palpation more exact, and at the same time more easy to attain.

It is now certainly known that while the head, breech or lateral plane of the fœtus may *offer* at the superior strait prior to labor, the vertex alone *engages*. The pains of labor are necessary to cause the engagement of the other presentations. The reason why only the vertex engages prior to labor is that the diameters of the vertex alone bear such a relation to the diameters of the pelvis as to make engagement possible, without the moulding effect of labor. It is also known that the head engages in a state of flexion—in obedience to the same law of accommodation which governs the attitude of the fœtus during pregnancy, and the imparted movements of the presenting part during labor. The knowledge of these two facts—that prior to labor, of the various possible presentations only the vertex engages, and that it engages in a state of flexion—is of immense importance in practising palpation. When the pelvic excavation is found full, that is, when the presenting part has engaged, we are at once assured that the vertex is presenting.

Since the vertex engages in a state of flexion, the occiput descends more deeply into the pelvis than the brow, and hence the brow is more accessible to the hand palpating from the abdomen; or, in other words, when the two hands palpate the abdomen above the occiput and the brow, if both hands are depressed, the hand corresponding to the occiput will sink more deeply into the pelvis, before it is arrested by the resisting occiput, than will the one corresponding to the brow. A further point to aid in the differentiation is that the brow feels harder to the touch than the occiput does. This may be owing to the relative thinness of that part of the scalp which covers the brow, when contrasted with that which covers the occiput, or it may be due to the more advanced degree of ossification of the frontal bosses as compared with those of the occiput; or, again, it may be that the greater accessibility of the brow makes it feel harder to the examining finger. I am inclined to believe that all three factors unite to create the difference in sensation imparted by touch. By thus discriminating between the brow and occiput, the position is determined.

It is important to know that the difference in the character of the articulations between the head and neck and the breech and trunk assists in differentiating between breech and head presentations in some cases. This differentiation is based on the wide range of mobility of the head, and the limited range of mobility of the breech. The head can be moved widely without disturbing the trunk, but it is not possible to move the breech independently of the trunk. Owing to these anatomical peculiarities the head can be ballotted, but the breech cannot. This cephalic *ballottement* can be obtained in head presentations (prior to engagement), in breech, and also in trunk presentations.

The thorough appreciation of these facts is of the greatest assistance in palpation. The practice, then, is based upon scientific data, and the method is rendered systematic and very uniform in its results.

The dress and position of the woman to be examined by abdominal palpation, are by no means matters of indifference. The less clothing worn, the better. Hence it is best to examine the patient in bed, and to see that she is clad only in her night-dress. When the skirts are simply pushed down below the nates, and the upper garments drawn up, to expose the abdomen, especially if corsets are worn, so much discomfort is caused that respiration is more or less disturbed, resulting in quickened respiration, which embarrasses the examiner.

The woman should occupy the dorsal decubitus, with the arms along the sides,

[1] Read before the Northern Medical Association, Dec. 14, 1888.

the thighs and legs extended, and the legs slightly separated. This allows the examiner to explore the false pelvis with ease, and the pelvic inlet with considerable facility. This position, which is that insisted on by Pinard, alone enables the examiner to explore the pelvic cavity. When the thighs are flexed upon the abdomen, and the legs on the thighs, the hypogastric region is so encroached upon by the thighs as seriously to embarrass the examiner in his manipulations, and even to prevent absolutely a satisfactory exploration of the pelvic cavity. The decubitus should be as nearly horizontal as possible—only a low pillow should be placed under the head. Occupying the horizontal decubitus, the woman has little temptation to contract the abdominal muscles, because no *point d'appui* is provided.

The bowels, and especially the bladder, should be emptied before beginning palpation. When the bladder is full the presenting part is inaccessible, and the sensations perceived are indefinite and untrustworthy.

The temperature of the room in which the examination is made should be such as not to chill the patient, who must lie with her bared abdomen exposed for some minutes.

The examiner's hands should be warm. It is well to wash the hands in warm water not only to secure the necessary warmth, but also to render the tactile perception more acute. Should palpation be attempted with cold hands, disappointment will surely result. The reflex contraction of the abdominal muscles from cold is prompt, and sometimes the shock causes the uterus to contract also—painless contraction of pregnancy.

Palpation can be practised only in the intervals between the contractions of the uterus; hence, when a contraction occurs during the examination, exploration must cease until this passes off. In practice this time can be usefully employed in listening to the fœtal heart-sounds, the location of which is of value in diagnosis, and the recognition of which establishes the fact that the fœtus is living.

While not strictly *apropos*, it is not unimportant to observe that the frequent recognition by the practitioner of these painless uterine contractions of pregnancy, during the routine examination of pregnant women, will effectually prevent such glaring errors in diagnosis as have occurred in the past, and are occurring even now. Were obstetric palpation generally practised, the pregnant womb would never be mistaken for a neoplasm, and unpremeditated Cæsarean sections would cease to occur.

With the foregoing principles in mind, and the conditions insisted on having been complied with, the examiner stands indifferently to the right or left of the woman, who is placed on a hard mattress sufficiently near the edge of the bed to be within easy reach. It is well to stand about opposite the umbilicus. Palpation is begun by estimating the thickness of the abdominal wall. This is done by picking up a fold between the thumb and fingers. The diagnosis of pregnancy having been established, it remains to determine the presentation and position of the fœtus. I have found it best to follow the teaching of Pinard, who examines after a uniform method, taking the bony pelvis of the woman as a fixed land mark. The horizontal rami of the pubes are sought for, and the hands, separated four or five inches, are placed upon the abdomen, the finger tips resting upon the upper margin of the pubic rami. This is easy under ordinary conditions, but when the abdomen is pendulous it is necessary first to raise up the sagging abdomen with the palms, before proceeding as indicated. The abdominal wall is then depressed from above downward and from before backward, the finger tips just grazing the pubic rami. The inlet of the true pelvis is thus explored and one of two conditions is found—that the cavity is *full* or that it is *empty*.

When palpation is practised in the last six weeks or two months of pregnancy, in the immense majority of cases the pelvic cavity is found full, the presenting part has engaged. Thus the diagnosis of vertex presentation is usually readily made. The presenting part is felt to be round, regular, and resisting. The head may be deeply engaged—and usually is in primiparæ—and immovable; slightly engaged and movable in the pelvic inlet; or it may simply rest at the pelvic inlet. When the head is found well engaged not only is the diagnosis of the presentation determined, but also that a proper relation exists between the diameters of the pelvic inlet and those of the fœtal skull. This condition is of prognostic as well as of diagnostic importance. Moreover, it is known that the presentation is fixed and definite—the uterine, fœtal, and pelvic axes coincide, accommodation is complete, and change of presentation impossible; only change of position can occur.

The diagnosis of the position is made by finding upon which side the cephalic tumor

is more accessible. This is determined by depressing the abdominal wall by the two hands, in the manner already described, until the palpating hands are resisted by the cephalic tumor. The hand upon one side will descend more or less deeply into the pelvic cavity, while that upon the other side will be arrested at a higher point. That portion of the head which is more prominent and accessible is the brow. These points are most easily determined in primiparæ, because in primiparæ engagement is more complete than in multiparæ—the vertex sinks into the pelvis, carrying the inferior segment of the uterus before it, at times almost to the pelvic floor; in which case flexion is very marked, and the different level occupied by the brow and occiput is easily determined.

When engagement is not so marked, as in the occipito-posterior positions, flexion is not so great, and the differentiation is correspondingly difficult to make. In my experience it has been at times impossible to say that the cephalic tumor was more accessible upon one side than upon the other, and I have been obliged to rely on other signs for the diagnosis of the position.

To sum up, then, when the pelvic cavity is full, the vertex is presenting. If the cephalic tumor is more accessible to the right, the position is left, and *vice versâ*.

Having explored the region of the superior strait and recognized the depending fœtal head, it remains to examine for the trunk, breech and extremities of the fœtus. Pinard recommends that the breech be searched for in the region of the fundus uteri, but I have usually proceeded to examine the uterine contents systematically, from below upward. In many cases it is possible distinctly to define the groove between the head and shoulders. Passing upward, palpating gently with the finger tips, upon one side at a time, a resisting plane, more or less broad, can be made out; this corresponds to one lateral half of the uterus. The fingers meet with little resistance in the other lateral half of the uterus. The abdominal and uterine walls can be more or less deeply depressed. Usually in making these manipulations the fœtal small parts can be felt. If the resisting plane is broad, it is the fœtal dorsal region; if not so broad, it is the lateral plane of the fœtus. In the one case the occiput is anterior, in the other it is posterior. Again, if the small parts are very accessible, that is, if they are anterior, the position is posterior; while if the small parts are accessible with difficulty, that is if they lie posterior in the uterus, the position is anterior. Should the fœtal dorsal region or lateral plane be separated from the uterine wall by liquor amnii, and not be easily reached by palpation, the manœuvre of Budin, which consists in depressing the breech—that is, increasing the natural anterior curvature of the fœtus—is useful. By this means the fœtal dorsal or lateral region is brought in contact with the uterine wall, and is then easily examined by palpation.

In head presentations the breech is found in the fundus uteri, in one or other hypochondriac region. The breech is best found by following upward the resisting plane of the fœtus (dorsal region, or lateral plane), which begins at the shoulder below and ends at the breech above. The breech gives the sensation of a voluminous, irregular body, less resisting than the head. The fœtal small parts are often felt in close proximity. The breech has not such a characteristic "feel" as the head.

Palpation after the method described usually gives positive results. When the sensations felt are typical, a diagnosis can be made of single pregnancy, of the presentation and position of the fœtus, and that pregnancy is not complicated by large intra-uterine or extra-uterine tumors. Cases of the class just considered form the immense majority of those seen in practice.

Instead of finding the pelvic cavity full, however, the palpating hands may find it empty. In this case, the lower end of the fœtal ovoid is usually found in one of the iliac fossæ, or it may be found resting on the pelvic brim, or above the plane of the superior strait. Almost never do the two extremities of the fœtal ovoid occupy the opposite flanks. Since one extremity of the fœtal ovoid is always in relation with the false pelvis, this region should be explored first. Whether the head or breech occupies the inferior uterine segment can be determined usually by recognizing the proper characters of these parts; and by finding the opposite extremity of the fœtal ovoid and the back, the exact location of the fœtus can be determined. If it is not possible to differentiate between the head and breech by recognizing the characters proper to each part, nor to locate the furrow between the head and shoulders, the head can be distinguished from the breech by a resort to *ballottement*. The head can be ballotted, but the breech cannot. As already pointed out, this fact is due largely

to the different character of the connection between the head and trunk and the breech and lumbar region. It is due partly to the fact that the head is spheroidal in shape, and hence touches the uterine parietes at one point only, while the breech is in contact with the wall of the uterus by an extended surface.

It seems to me that it will be sufficient to give the diagnostic signs of the first and third positions of presentation of the vertex, and to refer briefly to the other presentations and positions.

Presentation of the Vertex: First Position.—The patient having been placed in the proper position for palpation, and the conditions which promote success having been complied with, the examiner begins to palpate. The thickness of the abdominal wall is estimated by picking up a fold between the thumb and fingers. The horizontal rami of the pubes are then found, and the hands, separated four or five inches, are placed upon the abdomen, the finger tips resting on the rami of the pubes. The abdominal wall is depressed from before backward and from above downward, which allows the inlet of the pelvis to be explored by the finger tips. Usually the cavity of the pelvis is found full—occupied by a round, regular, resisting body, which can be nothing but the engaged head. This being determined, the hands are placed at a slightly higher level (nearer the umbilicus) and depressed as before, to discover which side of the cephalic tumor is more accessible. This side corresponds to the brow, the other to the occiput. In the first position of the vertex presentation, the brow is found to the right. The diagnosis of this presentation and position is made usually in this way very readily. The diagnosis is confirmed by further palpation, or, should the diagnosis of the position be doubtful at this point, it can be made by finding the location of the back, small parts and fœtal heart sounds.

The examination is continued by palpating the abdominal contents systematically, from below upward, making light pressure with the finger tips, first on one side, then on the other. A broad resisting plane will be found, in the first position, in the left half of the uterine cavity; while the fingers will sink deeply on the right side, depressing the abdominal and uterine walls. The plane which resists the fingers is the fœtal dorsal region. Resistance is not felt on the right side because the liquor amnii, which occupies the space between the curled-up body of the fœtus and the uterine wall, is readily displaceable. The breech is found continuous with the "resisting plane." In primiparæ, and in multiparæ with tense abdominal muscles, the breech is found usually in the left hypochondriac region, while in women with lax abdominal and uterine walls it is more likely to be found in the epigastric or right hypochondriac regions. Owing to the anterior position of the dorsum, the small parts are posterior and relatively inaccessible. (In practice, the diagnosis is confirmed by finding that the fœtal heart-sounds can be heard plainest to the left of the median line at a point about halfway between the umbilicus and the middle of Poupart's ligament.) Thus it is seen that the diagnosis does not depend upon the recognition of any one point, but upon the determination of the location of the various anatomical regions of the fœtus; and for this reason the diagnosis is very reliable.

In case the vertex has not engaged it is of little importance to determine the position of the fœtus, since under these circumstances the position is very unstable. It can be done, if desired, by locating the back, and fœtal small parts.

Second Position.—This position is very seldom encountered. The description of the diagnosis of the first position is applicable to that of the second position if the words "right" and "left" are transposed.

Third Position.—Owing to the less degree of flexion of the head in posterior positions the relative accessibility of the brow is not so marked as in anterior positions; hence the results gained are not so definite. Usually, however, it can be determined that the position is right by finding the brow to the left. This is confirmed by finding a resisting plane in the right side of the uterus, and by the absence of a resisting plane on the opposite side. The resisting plane, felt to the right is narrow—it is the lateral wall of the fœtus. The small parts are anterior and can be readily felt in the left side of the uterus The breech will be found in the right hypochondriac, epigastric, or left hypochondriac regions, according as the abdominal and uterine walls are tense or lax. (The fœtal heart is heard plainest far to the right of the median line.)

Fourth Position.—The description of the diagnosis of the third position is applicable to the fourth position, the words "left" and "right" being transposed.

Presentation of the Breech.—The pelvic cavity is found empty. The breech is found in relation with the false pelvis. If it be impossible to recognize the breech

by its proper characters the diagnosis can be made by finding the head at the fundus uteri. (The fœtal heart is heard at or above a horizontal line dividing the uterus into two equal parts.) The position is made out by locating the dorsum and fœtal small parts.

Presentation of the Trunk.—The pelvis is found empty. The long axis of the uterus is oblique and not parallel with the long axis of the body. One extremity of the fœtal ovoid is found in one iliac fossa and the other in the opposite flank. The dorsum or fœtal small parts are felt in relation with the anterior wall of the uterus. Pinard found the head in one flank and the breech in the other only twice in the 100,000 women examined by him.

Presentation of the Face.—It is practically certain that presentation of the face never occurs prior to labor. Those who have examined women per vaginam only, admit that primitive face presentations are exceedingly rare. Naturally these examinations have seldom been made until the advent of labor. The fact that Pinard has never met with a face presentation prior to labor is strong evidence that this presentation is produced after labor has set in.

The description of presentations of the vertex already given was restricted to women with normal proportions. Pinard states that in women having pendulous bellies (ante-version of the pregnant uterus) a special accommodation is found. The occiput is in relation with the middle of the iliac bone, and not with either the acetabulum or the sacro-iliac synchondrosis. The breech is found near the ilium opposite to the occiput, and the feet are felt very near the brow. That is, the fœtus is very much curved on itself, and a considerable part of the dorsum runs transversely across the uterus, instead of approximately parallel with its vertical diameter. A resisting plane is felt on each side of the uterus, and the elasticity of the liquor amnii is perceived as easily above as below. Unless this peculiar accommodation of the fœtus is known, a mistake in diagnosis is easy.

When the vertex presents in women whose pelves are deformed by rachitis (rickety flat pelvis) the head is found at the level of the superior strait or slightly engaged—depending on the degree of contraction. As is well known in this variety of contracted pelvis, the long, *antero-posterior*, diameter of the head is parallel with the long, *transverse*, diameter of the pelvis. Flexion is slight. The brow can sometimes be felt at a higher level than the occiput, and at times can be recognized by its marked hardness. The dorsum is felt in relation with one lateral wall of the uterus, the narrow lateral plane of the fœtus being directed anterior. The breech is found in the fundus when the uterus is not anteverted. The small parts are felt in the lateral half of the uterus opposite the dorsum.

In the other varieties of contracted pelvis, when the degree of contraction is at all great, the head rests at the level of the superior strait, and is freely movable by the palpating hands. It is impossible to force the head down into the cavity of the pelvis, *i. e.*, to make it engage, by making pressure from above. The same is true in cases in which the disproportion between the head and pelvis is due to abnormally large size of the head, as from hydrocephalus, being especially marked when the disproportion is great.

ERYSIPELAS OF THE PHARYNX AND FACE.

BY EDWARD P. DAVIS, A.M., M.D.,

OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL; PHYSICIAN TO THE FOULKE AND LONG ORPHANAGE FOR GIRLS, AND TO THE CLINTON ST. BOARDING HOME FOR WOMEN, ETC.

The following case, while not rare, furnishes a clinical study of practical interest:

R. F., 17½ years old, a robust girl of full development, had formerly had diphtheria and scarlatina. Examination of the pharynx, when in ordinary health, revealed slightly enlarged tonsils with chronic catarrh of moderate severity of the pharynx and posterior nares. She had, at intervals of 6 or 8 months, several attacks of tonsillitis from which she recovered under the use of sodium salicylate, and a gargle of boracic acid, potassium chlorate and glycerine. On Dec. 14, 1888, the writer's attention was directed to the patient who was said to be suffering from "a cold," contracted 48 hours previous. The face was flushed, the pharynx uniformly reddened and swollen, the tonsils enlarged: moderate constitutional disturbance was present. As the symptoms were those of previous attacks of tonsillitis treatment for that condition was ordered.

Twenty-four hours later the nature of the infection from which the patient suffered was apparent. The face exhibited the diffuse lymphangitis present in facial erysipelas; the pharynx was intensely reddened, uniformly swollen, without membrane; the

tonsils swollen, but not greatly in excess of the swelling of the surrounding parts. The lymphatic glands of the neck were enlarged and tender. A marked febrile disturbance existed, with severe frontal headache, backache, pains in the limbs and photophobia. The diagnosis of erysipelas of the pharynx and face, originating in a septic focus in one or both tonsils, was made. The subsequent history of the case confirmed the diagnosis. The temperature on the second afternoon rose to 105° F., and gradually declined to normal on the 14th day. The pulse ranged from 120 to normal; respirations from 30 to normal. Mild delirium, alternating with stupor, persisted for several days. The infection of the lymphatics extended over the nasal and pharyngeal mucous membrane, but did not invade the larynx; bronchitis of the larger tubes was present, but the parenchyma of the lungs was not infected. The mucous membrane of the gastro-intestinal tract shared in the infection, and gastric and abdominal pain, tenderness and distension were present. On the face the lymphangitis invaded the scalp; on the neck and trunk it extended slightly below the clavicle, over one shoulder. At no time was membrane present in the throat; the follicles of the tonsils were distended by sero-purulent fluid, and the mucous membrane of the pharynx became grayish and infiltrated with similar fluid.

As the attack declined in severity desquamation occurred on the face, and in the pharynx and nares. The patient expectorated and ejected from the nose a muco-purulent fluid, which left the surface of the mucous membrane a bright pink. The stools were voided with pain and difficulty, and were streaked with mucous and grumous coffee-ground material. A slight urethral and vaginal discharge was also present. Convalescence was established at the end of three weeks.

The treatment consisted in the regular and persistent administration by a competent nurse, of whiskey and milk, the amount of alcohol given varying with the pulse and temperature, as indicating the severity of the septic intoxication. High temperature was treated by sponging with alcohol and water; no antipyretics were given. Suppositories of glycerine were used to relieve constipation, and soap and water enemata were occasionally employed. Boracic acid was used as a local antiseptic; the conjunctivæ were douched with a saturated solution diluted one third; the pharynx was treated with a saturated solution in glycerine, employed as a gargle; the nares were thoroughly douched with a glycerine and water solution. An ointment:

Acid. boracic. pulv.	℥i
Lanolin	℥i
Vaseline	q. s.

was thoroughly employed in anointing the lips, nostrils and abraded surfaces on the face.[1]

Alcohol was the only constitutional antiseptic and cerebral sedative given; the quantity administered varied with the indications and effect desired. As the fever declined a mercurial purge was given, followed by salines. The urine was rich in urates and phosphates, with a trace of albumin. Easily digested food was allowed in abundance as soon as the condition of the intestines warranted its administration. The case was considered infectious and contagious, and was isolated: the apartments occupied were thoroughly fumigated and disinfected after the patient's convalescence: the patient received an antiseptic (carbolic acid) bath, and especial attention was given to cleansing and disinfecting the scalp and hair.

The point of practical interest to which attention is directed is the centre for septic infection afforded by an enlarged tonsil. In the case in question no caries of the teeth or jaw and no ozæna existed in which the infection could have originated.

It has been shown by numerous observers that "catching cold" is not an adequate cause of erysipelas of the face; while exposure to cold may cause congestion, predisposing to inflammation, yet the specific germ of septic infection is needed to produce erysipelas. Tissues in which necrosis of the cellular elements has occurred furnish a peculiarly favorable culture field for such infective micrococci. This has been especially well shown by Kaposi,[2] who considers the most frequent sources of facial erysipelas to be a carious tooth; a patch of facial eczema; lupus; scrofula or syphilis of the nose, or retro-pharyngeal abscess. Strümpell[3] regards nasal catarrh, acute or chronic, as a common predisposing cause of facial erysipelas. Koch and Fehleisen have shown

[1] Some samples of lanolin are too stiff for a convenient ointment, and can be mixed to advantage with vaseline or cosmoline.

[2] Pathologie und Therapie der Hautkrankheiten Erste Hälfte. 1886. § 406.

[3] Lehrbuch der Specieller Pathologie und Therapie der innerer Krankheiten. Erster Band, 1886. § 95.

the possibility of direct infection and contagion when the infective germ finds a favorable culture-field. It is for this reason that persons whose nasal and pharyngeal mucous membrane and cutaneous surfaces are intact may come in contact with erysipelas with impunity, while another who possesses a focus of former suppuration is readily infected. As the patient was in an institution in which other inmates were living who had formerly had tonsillitis or other inflammatory affections of the pharynx, jaws or nares, her isolation was necessary.

Regarding the treatment of such a septic infection, the value of alcohol is especially noteworthy, when combined with easily digested food. No other antiseptic can be introduced into the blood in efficient quantities without danger to the patient. The use of antipyretics which act by depressing the nervous system is contra-indicated in septic fever; in the present state of knowledge of pathology it is not known that fever is not a conservative process by which the spores of septic cocci are destroyed as soon as formed.[1] An antiseptic which can circulate in the blood, destroying septic germs, and in proportion to the dose exciting or exercising a sedative influence upon the cerebro-spinal centres, is needed in the treatment of septic fever. Among other objections to the depressing antipyretics is the fact that secretion and excretion are impaired by their use in large doses. In this connection Runge's method of treating puerperal septicæmia by alcoholics, baths and packs and forced feeding is instructive; his cases now number 20, with 15 recoveries.[2]

The local treatment of facial erysipelas is important, as Kaposi has shown. The mouth, pharynx, nares, and ears should be thoroughly cleansed and disinfected by an innocuous antiseptic, iodoform, thymol or boric acid.

A vaseline or lanolin ointment containing one of these antiseptics may be employed to advantage in carefully healing fissures or abrasions on mucous membranes or skin.

Erysipelas, or infection of the mucous surfaces of the body by Fehleisen's micrococcus, is sufficiently common to afford abundant opportunity for its clinical study, and with other septic infections offers some of the most interesting problems in modern pathology.

A FORMULA FOR CROUP.

BY J. B. JOHNSON, M.D.,
WASHINGTON, D. C.

The following formula has been a standard prescription of mine for croup for many years. It relieves all the symptoms of the disease with greater promptness and certainty than any other mixture I have ever used. I give it in teaspoonful doses to infants six or eight months old; and to children six and eight years old I give dessertspoonful doses every ten or fifteen minutes, until free emesis is produced; I also use it at longer intervals until a cure is established. The formula is as follows:

℞ Misturæ Acaciæ . . . . . f℥ij
Balsam. Copaibæ . . . . . f℥j
Ext. Ipecac. Fl. . . . . f℥j
Potassii Iodidi . . . . . ℥j
Pulv. Potassii Chlorati . . . . . ℥j

M. S. Shake well. Dose, a teaspoonful every ten or fifteen minutes until free vomiting ensues; and then continue the same dose, at intervals of a half-hour or hour, until the disease yields.

I have frequently relieved a croupy cough of twelve hours' duration, in three or four hours, by giving tablespoonful doses, every quarter or half-hour, of the following mixture:

℞ Potassii Iodidi . . . . . ℥j
Pulv. Potassii Chlorati . . . . . ℥j
Aquæ distill. . . . . f℥vj

M. S. Shake well and give a tablespoonful every quarter or half-hour until relief is attained.

—The *Boston Med. and Surg. Journal*, Jan. 17, 1889, says that the German societies of Brooklyn, N. Y., interested in the establishment of a German hospital, have appropriated about $10,000 from the regular society fund to the purchase of a hospital site in the 18th ward, near the routes of the Brooklyn Elevated and other city railroads. The twenty-seven parcels of land bought aggregate 50,000 feet or more.

—The *Western Druggist*, Jan., 1889, says that quinine, under a recent decision of the Illinois Supreme Court, is not a "domestic remedy" and cannot be sold except by a registered pharmacist. An Illiopolis barkeeper has been recently fined for selling it. In view of the late crusade of saloon-keepers against alleged dramselling-druggists, the compliment should be returned by prosecuting quinine-selling liquor dealers. Absinthe is also a drug, and an attempt might be made to suppress its sale also.

SOCIETY REPORTS.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, January 28, 1889.

The President, A. S. HUNTER, M.D., in the Chair.

DR. H. D. CHAPIN read a paper on

Septic Poisoning in Early Life.

Cases of septic poisoning in early life, he said, are conveniently divided into those which occur in the newly born and those which occur in older infants. In the newly born the seat of entrance of the poison is usually the umbilicus, and may, according to J. Lewis Smith, be by way of the vein or by way of the lymphatics. The abrasion giving entrance to the poison may be caused by the forceps; after birth and after healing of the cord, the genitals are likely to be the vulnerable point. The infection often starts as an erysipelatous inflammation upon the surface, and some poison enters the system, giving rise to inflammation of the peritoneum and other serous membranes, etc. In older children the upper part of the body, especially the scalp, mouth, etc., become the vulnerable parts. Pediculi, which cause the child to scratch and thus introduce matter from ulcers into the system, are not infrequently the cause. The germs when introduced in small quantity may be entirely or largely disposed of by the inherent vitality of the lymphatics, and cause only local symptoms; but if introduced in larger numbers constitutional symptoms develop. Dr. Chapin thinks aphthous mouth with small ulcers may be the source of septic poisoning, as also may otitis media purulenta, etc. In closely crowded apartments with imperfect ventilation, sewer-gas and foul air, the germs are constantly brought in contact with the air passages, and doubtless often give rise to mild forms of septic poisoning, which are commonly attributed to malaria.

The treatment should be prophylactic; but when septic poisoning has occurred, the seat of entrance of the poison should be sought for, cleansed, and healed, and, in addition, general measures are indicated.

DR. J. LEWIS SMITH thought the severest cases of septic poisoning in infants took place at the umbilicus. He suggested filling the umbilical fossa with iodoform in the newly born. He believes scarlet fever and diphtheria often prove severe or fatal on account of septic material finding entrance at the seat of lesions occurring in those diseases. Strict cleanliness and antisepsis should be observed. Vapor of carbolic acid, turpentine, and eucalyptus (the latter to mask disagreeable odor) should fill the room; and a spray of bichloride of mercury, in quantity sufficient for an internal dose, should be used in diphtheria, allowing it to pass on down the throat.

DR. A. H. SMITH urged the importance of stripping gelatinous material from the cord and thus hastening mummification.

DR. SIMON BARUCH read a paper on

The Value of Water in Therapeutics,

in which he sought to give an impartial review of its value as established by clinical evidence, and not simply to praise the water-cure system. During his service as army surgeon in the late war it was the custom to use water freely in dressing wounds, and the mortality from suppuration and gangrene was greater than has attended the more recent dry dressing. In laparotomy boiled water has been demonstrated to be of value. It is the author's belief that the antiseptics of the surgery of the future will be largely cleanliness, obtained by boiled water, and not so much by antiseptic drugs. The value of hot water as a styptic has been established; it is especially serviceable in *post-partum* hemorrhage. The marked value of vaginal douches in certain inflammatory conditions has been established by Dr. Emmet. Water is of benefit also in certain skin affections, but is contraindicated in eczema. The treatment of otitis media purulenta by irrigation has been abandoned for the dry treatment, and with great advantage. The custom of employing vaginal irrigation in normal labors has been shown to be bad.

Speaking of the internal use of water, the author passed by its diuretic and diaphoretic effects, and first considered the advantages of washing out the stomach in dyspepsia and indigestion. In recent cases a few washings with some care in diet often cure; but in chronic gastritis the treatment has to be continued for some time. The sipping of hot water at intervals before breakfast is of benefit in indigestion, but it should not be taken just before the meal. Of recent date also is the introduction of the treatment of gastric disturbance in infants by washing out the stomach. In summer diarrhœa no treatment is more beneficial

than irrigation of the large gut. It is also of value in catarrhal jaundice.

Cold water to the surface of the body acts chiefly through mechanical and thermal influence, and has a wide field of usefulness. The reaction which follows the application of cold water to the surface has a remedial effect in many affections, among which are certain neurasthenias in robust patients; it takes the place frequently of so-called tonic medicines. Dr. Baruch reviewed the use of cold or tepid water in the reduction of the temperature of the body in fevers, and the mortality statistics of typhoid fever, according as the disease had been treated by the usual method or by the employment of the bath. The usual mortality, he said, has been from 21 to 26 per cent., or higher, whereas Brandt and others show a mortality rate under the treatment by water of only 7 per cent. or less. He concluded his paper by strongly recommending Brandt's method of treating typhoid fever. The bath employed by him has been of a temperature of 65° F., but he suggested that it it may be better to employ a higher temperature, gradually lowering it by adding colder water, which, of course, would necessitate leaving the patient in the water a longer time.

Dr. J. Harvie Dew read a paper on the same subject, viewing it rather from the standpoint of physiology. At the beginning, he said, it is necessary to recognize the following facts: 1. The chief component part of human bodies in fair condition is water. Its relative proportion to all the solid constituents has been estimated at from two-thirds to three-fourths the entire weight. 2. Water constitutes almost the total volume of each of the circulatory fluids, including those of digestion. 3. It is the essential medium by which digestion is accomplished, absorption is made possible, and the transportation of the elements of nutrition to the various tissues of the body is made easy. 4. As water enters so largely into the composition of the tissues, it becomes of corresponding importance to every process of assimilation. 5. Water is not only the medium of transportation of nutritive elements introduced by absorption, but it is also the medium by which all waste matters are held in solution and are conducted to their several points of exit. 6. Observation and experiment have shown that from three to four pints of liquid food are required to maintain the normal functions and weight of an individual weighing from 140 to 150 pounds. 7. It is a clinical fact that wherever we find persons thin in flesh it can be noted that by habit or for other reasons they are taking very small quantities of liquid food; while, on the other hand, all well preserved or fleshy persons will be found to be copious drinkers of fluids in one form or another. 8. It is also a clinical fact that in every morbid or diseased condition of the system, whether organic or functional, primary or secondary, the functions of digestion, absorption, assimilation, secretion, and excretion, embracing elimination, become in one way or another disturbed—sometimes one or more of these functions, at other times all of them to a more or less degree in the same patient. 9. It is not only important to note these disturbances as they are exhibited in well defined diseases, but it is equally important to recognize the fact that a very large proportion of the diseases and troubles to which the human body is liable have their origin primarily and absolutely in some improper performance of these functions.

From these facts one would recognize at once the necessity for a plentiful supply and use of fluids, both in the maintenance of health and in the restoration thereto from disease.

The discussion of these two papers was made the special order of the next meeting.

Foreign Correspondence.

LETTER FROM AUSTRALIA.

The Theories and Treatment of Snake-Bite in the Australian Colonies.

In an interview with Dr. Creed, of Sydney, I gained the following opinions on the treatment of snake-bite. Dr. Creed said:

From the experience which I have had of cases of snake-bite in New South Wales, and from inquiries I have made as to the particulars of others which have occurred in the practice of my friends who have kindly given me an account of them, I have been obliged to arrive at the conclusion that, with the exception of the species of *Hoplocephalus*, especially the "large-scaled snake," or, as it is called in Tasmania, the Diamond snake (*Hoplocephalus superbus*), and the brown banded or tiger snake (*Hoplocephalus curtus*), the death adder (*Acanthophisantaretica*), the brown snake (*Diemenia superciliosa*), and a large and

vigorous specimen of the black snake (*Pseudechis porphyriacus*), the danger of death from the effects of the bite of the numerous venomous snakes common to the colony is very much exaggerated, and that in the majority of cases showing serious symptoms, these symptoms are really the effect of intense fear and not of snake poison.

The doctor says that the essential object to be attained in the treatment of every bite from a venomous snake is the prevention of the absorption of the poison, and this can be done only by the stopping of the circulation as quickly as possible between the bite and the heart, and the prompt and efficient excision of the punctured part to such a depth as shall insure either the absolute removal of the injected poison, or at all events, its exposure to such an extent that it can easily be removed by washing with the nearest attainable fluid, preferably water. He strongly insists on the advantages of the excision of, instead of incision into and about, the puncture caused by the teeth of venomous snakes, for the following reasons: As the longest poison-fang of the largest Australian snake is less than one-fourth of an inch in length, excision of the very lowest point of the puncture is easily practicable by any intelligent person, without danger of causing more serious hemorrhage than can easily be controlled by the application of a pad. If done in this way the whole of the poison will be removed. On the other hand, incision made into and about the wound may or may not remove the venom, which might easily be retained at the original spot into which it was injected by the bite, if the cut made did not actually enter into and freely expose it. In addition, the danger from hemorrhage would be very much greater from the wound made by the incision, as the point of the knife would probably enter to a greater depth than the wound made in excision. In fact, unless the operator has a fair knowledge of anatomy, he might easily in many places wound an artery lying comparatively superficially, and cause death by hemorrhage in a few minutes.

With regard to sucking the wound, the entire removal of the poison by its means is problematical, and such treatment is not without danger to the person sucking. Unless made by a person with some knowledge of anatomy, he thinks the excision should be made by pinching up the parts to be cut away, and then removing them with the middle of the blade, and not by inserting the point of the knife and cutting round the bite. The wound should be well washed and moderate bleeding encouraged. It would be well to wash it with a weak solution of permanganate of potash, or it might have an application of strong nitric or carbolic acid, or the actual cautery. The permanganate is probably an antidote if brought in direct contact with the poison, but when thrown into the general circulation it can be only of little if any use, for it will attack not only the snake poison but will oxidize all organic matter with which it comes in contact. After the ligature is removed the patient should be carefully watched and symptoms treated, the best stimulant being ether under the skin. Compulsory exertion or walking the patient about is forbidden. This notion of keeping the patient awake is carried even to a ludicrous extent. In a case in New South Wales the local brass band was hired to play their most fierce tunes to keep the patient from sleeping; the patient made a recovery from the bite as well as from the infliction of the music. Dr. Creed uses alcohol for the treatment of the symptoms of exhaustion but not as a special treatment of the poison.

By experiments made by Mr. Krefft, in Sydney, it has been demonstrated that no effect follows the infliction of a bite by one of the most venomous snakes either on itself or on another venomous snake of the same or a somewhat similar class. From this Dr. Creed argues that if a physiological antidote is to be discovered, it must be sought in this peculiar property inherent in the snake, which can hardly be merely consequent on structure, but may be the result of some substance diffused in the snake itself, which diligent research may demonstrate to be capable of isolation, and, if so, of use in the treatment of snake-bite. Dr. Creed is of the opinion that in order to prevent fear from acting harmfully on the patient he would when needed use ether as an anæsthetic. He would keep the patient barely unconscious for an hour or two, then allow him to recover enough to judge of his condition, watching pulse and respiration all the time carefully. If necessary he would bring the patient again and again under the influence of the ether, so long as might be required.

He feels there is a germ of useful treatment in this suggestion. I am told that the treatment of snake-bite by ether has been tried by Dr. Bancroft, of Brisbane, with most encouraging results. Dr. Creed feels that there has not been up to the present time a physiological antidote found for this terrible poison of snakes. This is not the opinion

of other members of the profession, and I now ask your attention to views held by a prominent physician of Victoria.

An interesting article on snake-bite and its treatment was read recently by Dr. Augustus Mueller before the Victorian Medical Society. The doctor stated that his experience and observations have made him acquainted with the poison of the black, the brown, and the tiger snakes only, and he did not extend his views to the poison of any other varieties of Australian snakes, nor for those of America and India. Inferences might be drawn that the antidote he suggested would be useful in all; but inferences were not proofs.

To be brief, I will state that the doctor's theory is that the poison of the snake does not act as a special blood poison; all the symptoms are due to deficient nerve action. The insidious venom travels quickly to the nerve centers, affecting in rapid succession the anterior columns of the cord, the vaso-motor centers of the brain, and causing paresis and paralysis of the muscles of the lower extremities, accompanied by rapidly diminished force of heart action and blood pressure, and in a very short time by sleep, which in severe cases deepens into coma; the latter sometimes remains till death, but more frequently passes off again, even in fatal cases. The usual method of death is by syncope. Dr. Mueller then made some interesting comparisons between the effects of the poison of the Australian and the Indian snakes. Both are without doubt nerve poisons. The Australian snake-poison seems more diffusible and develops its effects more quickly, and is distributed uniformly over the whole motor system. It is on this account, and also on account of the smaller quantity of poison at the disposal of Australian snakes that their bite is less frequently fatal than those of the Indian snakes of the East Indies.

The poison of the latter snakes, especially of the cobra, seems less diffusible, and takes a longer time as a rule to develop its effects; but once fully developed the course is much more quickly fatal, owing to the fact that the poison concentrates its action on special nerve centers, instead of being equally distributed over all. Dr. Mueller has had thirty years' practice in a district in which snakes abound, and he has unusual opportunities of studying the effects of snake-bite, both on men and the lower animals. He tells how he came to have his attention called to the use of the antidote that he now so strongly recommends, viz., strychnia. Strange to say it was in a case of spider-bite in a child two years old. He asserts that effect of spider-bite differs only in degree from that of snake-bite. Incidentally it may be mentioned here that there are a number of fatal cases of spider-bite on record in the Colonies; in Queensland they are not at all of very rare occurrence. In commenting on this case the doctor says he was at once struck by the close resemblance, if not identity, of symptoms here present with those of snake-bite—loss of power in the legs, extreme pallor, coldness of skin, feeble heart action, with pulse scarcely perceptible at the wrist, dilated pupils insensible to light, and inability to move either arms or legs.

Treatment was begun with the usual orthodox remedies—eliminative, stimulating, alkaline, etc., etc., but all failed. The collapse increased rapidly, respiration became difficult, eyes glassy, heart's action barely perceptible, pulse gone at the wrist. In short, the patient would die in a few moments to all appearances. Now came to me a happy thought, says the doctor; like a flash it passed through my mind that the child's inability to walk soon after being bitten might have been caused by the subtle poison exerting a specific depressing effect on the motor cells in the anterior columns, gradually extending over the rest of the motor and also the vaso-motor centers. All the ominous symptoms thus found a ready explanation, and strychnia suggested itself as the remedy for this condition of things. To use his own words, "I hastily procured some strychnia, and injected ten minims of the official solution into the arm. In a half hour's time my little patient was sitting up, snatched, I have reason to believe, from the very jaws of death." He then relates a case in which he used this remedy in a venomous snake-bite, with equally good success. In another case he produced, through the agency of the strychnia, a marvellous change in a desperate case in less than an hour, watched the patient for a number of hours and then gave his sanction to his going home. The lad felt strong and entirely well, mounted his horse and rode off; but he died next morning before the doctor could reach him. "I did not know then, as I do now, that even strychnia is more quickly decomposed and thrown out of the system than the snake-bite poison and that the latter will lurk about in the holes and corners of the system and resume its work of destruction as soon as the antagonist is removed that kept it in check. I had injected into

the system of a mere boy, within half an hour not less than one-third of a grain of strychnia; but even this comparatively large quantity was evidently only just enough to counteract for a time, and as long as it lasted, the deadly venom. If I had only dared to push the use of the drug a little further, until it produced the usual symptoms in a moderate degree; if I had only directed it to be taken internally, from time to time in ordinary doses as I do now, after the painful lesson this case gave me, I have not the remotest doubt, from what I have seen of its action since, that the life of this lad would have been saved."

Notwithstanding the fatal termination of this case, however, his faith in the antidote was confirmed rather than shaken, for he felt convinced that its failure was wholly and solely due to the mistake he made in not continuing in it small doses, until it produced slight muscular spasms. Though the lad had received within a half hour four times the quantity we are allowed to give in ordinary practice in one dose, it was evidently not sufficient to counteract completely and effectually the deadly venom with which his body was saturated, but only checked it for a time.

Dr. Mueller feels quite confident that snake-bite and strychnia react on each other in the human organism with the unerring certainty of two chemical tests. The dose of the antidote must be in proportion to the severity of the symptoms, but even a little more than is required can do no harm, for its effects pass away very quickly in snake-bite. A few muscular twitches, a little stiffness about the neck or about the mouth, are nothing compared with the horrid sensations which the deadly snake-poison produces.

Dr. Mueller then produced some collateral evidence in regard to this treatment. In China and India where the terrible raja commits its destruction of human life each year, a famous antidote with the natives is a pill which is called in China Nooang. On examination this is proved to belong to the strychnos family; that is, the pill is made from a plant of this family. Another famous antidote is the nuts of the Simaba Cedron, among the natives of Central and South America. Its active principle resembles strychnine; it probably resembles more closely quassine, yet this leads us to the point that it is among the bitter tonic alkaloids that we are to look for the antidote for snake-poison. The doctor concludes with his opinion of alcohol: "Stimulants are, no doubt, of use in stimulating the heart; but their action is transitory, because they do not attack the enemy in his stronghold; they do not permanently raise and alter, as the strychnine does, the depressed and partly suspended function of the motor centres, which lies at the root of all the mischief, and is, beyond doubt, the cause of death in snake-bite."

C. C. Vanderbeck.

Periscope.

Hereditary Syphilis.

The Vienna correspondent of the *British Med. Journal*, Jan. 12, 1889, states that at a recent meeting of the Imperial Royal Society of Physicians of Vienna, Professor Neumann read a paper on hereditary syphilis. The questions with which the lecturer dealt were the following:—1. What is the condition of the offspring when the father and mother were healthy at the time of conception, and the mother became infected at a later date (pure post-conceptional syphilis)? 2. What is the effect of post-conceptional syphilis with reference to the offspring when the father was already syphilitic at the time of procreation? 3. What is the effect of post-conceptional syphilis with reference to the offspring when the condition of the father's health at the time of procreation is unknown, and the mother was healthy at the time of conception, and became infected at a later date? 4. What is the condition of the offspring when the infection and the conception took place at the same time? And, 5, when the infection of the parents occurred before conception?

Professor Neumann's paper was based on cases most of which he had observed during eight years in his clinic. Of these only 102 were available for the purpose he had in view, as accurate data concerning the offspring could not be obtained in the rest. The physicians of the three obstetric clinics of the General Hospital and those of the Vienna Foundling Hospital also took an active part in the investigation. With regard to pure post-conceptional syphilis, Professor Neumann had observed 11 cases; of these 5 patients were healthy, and the rest, in part, presented the appearances of syphilis, and, in part, miscarriage occurred. As regards post-conceptional syphilis, where the father was syphilitic, 5 children were found to be healthy, 2 children were affected with syphilis, and in 5 cases miscarriage had occurred. In the cases of post-con-

ceptional syphilis, where the father was unknown, there were 10 healthy, 1 syphilitic, and 7 dead children; 2 children were still under treatment. In the cases in which conception and infection took place at the same time, 15 children were healthy, 1 died of peritonitis, 4 were syphilitic; the fate of these cases could not be ascertained, and in 21 instances still-birth occurred. Among 25 cases of syphilitic infection before conception, there were 10 healthy children, 8 cases of miscarriage, and 4 of maceration; 3 were still under treatment.

Professor Neumann arrived at the following conclusions: 1. A syphilitic mother may convey the disease to her offspring at any stage of her affection, whether the infection has taken place before or after the conception. 2. A mother who has contracted the disease after conception sometimes transmits it to the fœtus. In the case of pure post-conceptional syphilis the transmission of the affection to the child is extremely rare, especially when the mother has become infected in the last months of pregnancy. 3. When the infection of the mother has taken place after conception, and the father was syphilitic at the time of procreation, the effect on the offspring is greatly intensified; the children in these cases die *in utero*, or are born with signs of syphilis. 4. In the case of post-conceptional syphilis, where the infector is unknown, the proportion is the same as in pure post-conceptional syphilis; syphilis acquired in the last months of pregnancy is usually transmitted to the offspring. 5. When infection and conception occur at the same time, the children die in one half of the cases. It is nevertheless remarkable that a great part of the offspring remain free of syphilis, in spite of the fact that the disease was in an active state in both the parents at the time of conception. This disproves the assertion that a healthy child can never be born when both parents are syphilitic at the time of conception. On the other hand, the assertion that healthy children are born only when the syphilis of the parents is seven years old, is also negatived. 6. In the case of infection before conception, the period at which conception occurred has to be taken into account; the longer the interval between infection and conception, the more favorable is the prognosis for the offspring. 7. The offspring has the best chance when the mother only contracts syphilis in the last months of pregnancy, while the father was healthy at the time of procreation; the same is also true of the offspring of parents suffering from tertiary syphilis. The offspring has the least chance when infection and conception have occurred simultaneously, or when the father was suffering from recent syphilis at the time of procreation. 8. This last observation also elucidates the question as to paternal syphilis. It is especially the cases in which the father was syphilitic at the time of procreation, and the mother became infected only after conception, and the child was soon after the infection born in a macerated condition, which prove the extremely injurious nature of paternal syphilis. This is opposed to the observations of Boeck and Dewere, who state that the child of a syphilitic father is always healthy.

These data, concludes Professor Neumann, show the sad fate of the children of syphilitic parents, as, out of 109 cases, only 44 were born healthy; and, according to inquiries made by Dr. Friedinger, director of the Vienna Foundling Hospital, only the minority of them live. Hereditary syphilis must, therefore, be considered one of the most terrible plagues of infant life.

Two Cases of Thyrotomy for the Removal of Malignant Disease of the Larynx.

At the meeting of the Clinical Society of London, Jan. 11, 1889, Mr. Butlin read notes of these cases. In pursuance of an opinion expressed by him in a previous paper, that it is not necessary to remove the cartilaginous or bony framework of the larynx in certain cases of intrinsic carcinoma of the larynx which are suitable for operation, two cases were reported. The first was a case of squamous-celled carcinoma (epithelioma) of the larynx in a woman 27 years old. The thyroid cartilage was divided in November, 1887, and the disease was cut and scraped out. She made a good recovery, and was well a year later, and free from every sign of cancer. The second was a case of the same disease in a man 51 years old. A similar operation was performed in 1888. The man recovered without hindrance, and was well in September. The author pointedly drew attention to the comparatively trivial nature of the operation in cases of malignant disease of the larynx of limited extent. In another instance in which he performed an exploratory thyrotomy in a man advanced in years, and found the disease too extensive for removal, he closed the wound, and the man recovered and left the hospital wearing a tracheotomy tube.—*British Med. Journal*, Jan. 19, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.00**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE DANGER OF CALOMEL INJECTIONS.

The recent studies in connection with the use of calomel injections in the treatment of syphilis have led to a revival of interest in this subject on this side of the Atlantic. But there are two reasons why those who are not yet committed to it may hesitate about adopting this method. One of them depends upon the fact that so eminent a syphilographer as Neumann, of Vienna, has recently pronounced against the general utility of calomel injections, and the other is that these injections may be dangerous to health or life.

Attention has recently been directed to this point by an article by Prof. J. W. Runeberg, of Helsingfors, in the *Deutsche med. Wochenschrift*, January 3, 1889, who refers to a few cases of mercurial poisoning caused by the medicinal administration of salts of this metal, and describes in full a case coming under his notice in which death was attributed, with much show of reason, to the absorption of mercury from points at which calomel had been injected.

The form of disease caused by accidental and chronic mercurial poisoning is usually that of an acute dysentery, and this was seen in Runeberg's case, while the autopsy disclosed the presence of a cavity containing unhealthy pus and a considerable quantity of mercury.

The case referred to indicates that one of the chief merits of the hypodermic use of calomel has associated with it a feature of danger. It is an advantage to have a method by which mercury can be administered by the physician with the expectation that it will be gradually absorbed; but the disadvantage is that the rate of absorption is not determinable, and some injections may be carried into the system promptly, while others may be taken up slowly and produce, with later ones, a culminating effect. And if such an effect makes its appearance, it is no longer possible to limit it by discontinuing the administration of the medicament. The quantity already in the body cannot be withdrawn, and it may continue poisoning the system long after it was first deposited.

These dangers deserve consideration, although in practice they have not proved to be very imminent. The cases of mercurial poisoning caused by calomel injections are very few and most of them have occurred in persons in an anæmic condition, predisposed to general disturbances. Still in one case, reported by Kraus, the patient was in good condition, and it must be remembered that syphilitics are not rarely in this very state and that always when they are so, and generally when they are not, some other way of administering mercury may well be chosen for them.

TETANUS NEONATORUM.

There was a time when tetanus of the new-born was so frequent that it was more or less an object of fear to physicians and parents. But in these days it has become so rare that it is hardly ever taken into consideration in estimating the perils of the first period of life. When it occurred, in former times, it was generally attributed to traumatism, and charged to improper management of the stump of the divided umbilical cord. Nowadays the germ theory of disease has come in to suggest a totally different conception of the nature and mode of origin of tetanus, and on the one hand we are asked to make our views in regard to it conform to the possibilities of infection with the germ found in earth by Nicolaier, and on the other hand we are confronted with the claims of Verneuil that tetanus is of equine origin and can always be traced to some direct or indirect infection from horses.

The arguments in support of both of these theories have much that is plausible about them, but nothing which to a keenly critical mind can be said to be conclusive. Both earth and horses are widely enough distributed to make it possible to invoke either of them to explain what takes place in almost any land; and certain experiments have been performed which indicate that tetanus may be produced in some of the lower animals with matters derived from the soil or found where horses are kept. But, none the less, the subject is still involved in much obscurity, and cases of tetanus in human beings occur which are as inexplicable to-day as were those which were observed many years ago.

An illustration of this fact is found in a recent study of trismus neonatorum, as it is seen in Iceland and in the Faroe Islands and the Hebrides, by Dr. H. Labonne, the results of which are published in the *Gazette Hebdomadaire*, January 11, 1889. Dr. Labonne makes the mortality from tetanus neonatorum in these islands range from thirty to sixty-seven per cent. In studying the causes of this frightful mortality he finds nothing to support the theory that the tetanus neonatorum found here is due to infection with a microbe, although he hazards a guess that the birds which furnish so much of the food of the natives, and so much of their bedding, may also supply them with some bacterium of tetanus. On the other hand, certain practical experiments which he cites indicate that the almost exclusive use of the flesh and oil of birds as food by nursing women brings about states of the milk which directly or indirectly induce tetanus in their nurslings.

The report of the investigations of Dr. Labonne is interesting, although it is not conclusive. It would be more valuable if it gave an account of the management of labor in the lands he visited, and the entire care of infants during the first days of their life. Both of these matters are of great importance in estimating the probable cause of any disease like trismus neonatorum; and without a knowledge in regard to them it would be impossible to form a rational theory of the etiology of the disease.

TREATMENT OF PUERPERAL SEPSIS.

Grave septic intoxication during the lying-in period is one of the most formidable conditions which confront the medical man, and one which sometimes puts his resources to the sharpest proof. For this reason it is desirable to give the widest circulation to any method for the treatment of puerperal sepsis which seems, on its face, to be rational and to have stood the test of experience in a sufficient number of cases.

Such a method has been in use for some time by Prof. Max Runge, of Göttingen, and is described in full in the *Deutsche med. Wochenschrift*, Jan. 3, 1889. In brief, the method consists in the employment of the customary local treatment, with the addition of lukewarm baths and the administration

of large doses of alcoholic liquors and full nourishment. Runge calls attention to the improvement in the prospects of women with puerperal sepsis which came with the introduction of an intelligent method of local treatment, and the comparative powerlessness of general medication. Of all the medicaments used in this condition, he thinks alcohol to be the only one of real value. Antipyretics he unqualifiedly condemns, as generally useless and often dangerous. This for two reasons: One, that the fever in puerperal sepsis is not usually of a high grade, and that mere elevation of temperature is a symptom which does not demand active interference; and, two, that antipyretics almost invariably ruin both appetite and digestion.

On the other hand, he finds that the administration of large quantities of wine and brandy, and the use of one or more lukewarm baths (22° — 24° Reaumur, or 82° — 86° Fahr.), improved the appetite of his patients so that it was not difficult to get them to take large quantities of nutritious and satisfying food.

The quantity of alcohol which may be given to a patient with puerperal sepsis may be gathered from the fact that one of Runge's patients took within a week over ten bottles of port and Madeira and about two quarts of Cognac. It is noticeable that even such large quantities of alcohol do not produce symptoms of intoxication, and that intolerance of large quantities is usually a sign of beginning convalescence.

As to the baths, Runge used them—not to reduce temperature, but to improve the general condition of his patients and to increase their disposition to take food. The idea of placing a lying-in woman in a full bath may seem startling to others; but Runge has never seen it do any harm, and has always seen it do good. The operation to be successful must be conducted by a skilled nurse or a physician, the temperature of the water and of the room must be right. The bath may last from three to eight minutes, and it is to be used according to the indications. The most that Runge ever administered was four in a day; usually he found one or two sufficient. The highest number he used in any one case was nineteen, in the majority of his cases from five to seven baths were sufficient, and in some of his cases only two or three were used.

The treatment outlined above is presented to his professional brethren by Prof. Runge in a manner which cannot fail to impress any one who reads his paper. In it there is no attempt to overrate the value of the method, and the whole argument bears the impress of careful thought, close observation and wise deduction. In theory his method commends itself to one's judgment, and in practice he has found it successful. We believe our readers will find it to their interest and helpful to their patients if they will give the method a trial, remembering that it can be expected to succeed only when combined with judicious local measures.

REGULATING THE SALE OF MILK.

We call attention to the suggestions—which are published in this number of the Reporter—made by a Committee of the Board of Health of Philadelphia in regard to a law to regulate the sale of milk in this city. The fact that more than two hundred and fifty thousand quarts of milk are used in Philadelphia every day indicates the importance of some such legal regulation of its sale as is here proposed. Our only comment on the plan of the Committee is that it might well be incorporated in and assimilated with a more general law, securing a systematic inspection of all articles of food and drink. If such a measure could be adopted soon, it would be better than a law for only one article. But if the former is not attainable at present, we hope a carefully prepared law in regard to regulating the sale of milk may speedily be passed.

An Abrupt Ending.—We have information from a trustworthy source that the official connection of Dr. John B. Hamilton with the *Journal of the American Medical Association* terminates this day, February 9. This sudden relinquishment of an office which he entered upon so recently will be a cause of surprise to those who have followed his vigorous editorial policy for the past six weeks. The reason for the step has not reached us when this note is written, but it may be public by the time it is printed.

The Middleton Goldsmith Lecture for 1889 will be delivered by Dr. Reginald H. Fitz, Shattuck Professor of Pathology in the Harvard Medical School, in the hall of the New York Academy of Medicine, on Saturday, February 16, at 8½ o'clock P. M. The subject will be: "Acute Pancreatitis, with an especial consideration of Pancreatic Hemorrhage, Hemorrhagic Pancreatitis, and Subperitoneal Fat Necrosis."

British Stupidity.—The *British Medical Journal*, Jan. 12, contains a letter from a correspondent in Paris, in which the prizes awarded by the French Academy of Sciences are mentioned. In this letter the following statement occurs: "The Prix Cuvier in Geology was awarded to Mr. Joseph Leidy, of Harvard University." This statement is no reflection upon the fame of Dr. Leidy, but is rather an illustration of editorial ignorance or carelessness.

The Doctor's Badge.—The *Medicinische Monatsschrift*, January, 1889, turns its attention to the question of a distinguishing mark for physicians, which has been seriously discussed during the past year by some of the medical journals. It quotes the *Medical World* as asking those who have courage enough to make themselves heard on this subject, and adds: "We accept this invitation, but would prefer to substitute for the olive green coat proposed by the *World*, a gray one. Instead of the letters M. D. on the collar, we would regard as more practical large ear trumpets of the same material, as a distinguishing mark of the bearer which would be visible from a great distance, and because they would serve as collectors of sound vibrations and facilitate the approach of the call of suffering fellow men to the membrana tympani of the wearer."

Election at the University of Pennsylvania.—At their meeting on Tuesday, February 5, Dr. J. William White was elected Clinical Professor of Surgery, and Dr. John Guitéras was elected Professor of Pathology and Morbid Anatomy.

Dr. John Guitéras is a native of Cuba, where he received his preliminary education, graduating from the Medical School of the University in 1873. In 1879 he was appointed by the President of the United States a member of the Havana Yellow Fever Commission, and took charge of the investigations in morbid anatomy. In 1880 he was appointed in the Marine Hospital Service, serving in St. Louis, New Orleans, Key West and Charleston. He was ordered by the Government to investigate epidemics of yellow fever in Vera Cruz, 1883; Key West, 1887; Florida, 1888. Dr. Guitéras has lectured in various medical colleges, and has made valuable contributions to medical science. In order to accept the Chair of Pathology he will resign his commission as Passed Assistant Surgeon U. S. Marine Hospital Service.

Dr. J. Wm. White, the new Professor of Clinical Surgery, is a Philadelphian, and was graduated at the University in 1871. Since then he has been surgeon to several hospitals in Philadelphia.

Besides these changes, a Clinical Chair of Orthopædic Surgery in the University Hospital was created, and a Chair of Histology and Embryology in the Medical Department. The former position will be occupied by Dr. De Forest Willard, and the latter by Dr. George A. Piersol.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A COMPEND OF THE DISEASES OF THE EYE; INCLUDING REFRACTION AND SURGICAL OPERATIONS. By L. Webster Fox, M.D., Ophthalmic Surgeon to the Germantown Hospital, etc., and Geo. M. Gould, M.D. Second edition revised and enlarged, with 71 Illustrations. Philadelphia: P. Blakiston, Son & Co., 1888. Small 8vo, pp. 164. Price $1.00.

That this little book has grown in usefulness there can be no doubt. Nearly all of the chapters have undergone revision, and many have gained by rearrangement. Treatment has been brought to date, and puzzling technicalities have been carefully replaced by either proper terms in full or by common expressive equivalents. Of the newly added cuts, however, all but one are taken from Meyer, without any indication that they have been borrowed.

Taken as a whole, the book is a good and trustworthy guide for its intended readers—undergraduates and busy general practitioners—but to them it is only fair to say, in the authors' own words: "Cultivate a habit of close and accurate observation of the eye. The successful ophthalmologist often suspects or bases diagnoses upon a perception of subtle and delicate differences in the external appearance of an eye that he would have difficulty in explaining to another"—as this is the only way by which they may hope to arrive at correct diagnosis, proper prognosis, and judicious treatment in cases of ophthalmic disease.

ELEMENTS OF PRACTICAL MEDICINE. By Alfred H. Carter, M.D., Lond., Physician to the Queen's Hospital, Benningham, etc. Fifth edition. Small 8vo, pp. xvi, 472. London: H. K. Lewis, 1888.

The purpose of this book is stated by the author to be: to provide students with a simple introduction to the study of systematic medicine, and to bring the essentials of the subject clearly and tersely within the grasp of those unable to master larger treatises. It is high praise to say that Dr. Carter has attained his object. His book is both terse and clear; and its terseness is not secured by sacrificing anything essential to such a work. His descriptions of diseases and morbid states are simple and yet full enough to be very useful, and his recommendations in regard to treatment are judicious and easy to remember. He avoids excess of detail in the former, and in the latter he lays down general principles and has not burdened his book with prescriptions.

As a whole his work is excellent, and would prove of value to students if its reading were made to accompany their attendance on didactic and clinical lectures. Equally is it calculated to be a help to busy practitioners—especially those who have not the time or inclination to consult elaborate treatises.

—Messrs. J. B. Lippincott Company announce to the profession the publication of a Cyclopædia of the Diseases of Children, medical and surgical, by American, British, and Canadian authors, edited by John M. Keating, M.D , in four imperial octavo volumes; to be sold by subscription only. The first volume will be issued early in April, and the subsequent volumes at short intervals. This is the only work of the kind that has been published in English.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

206. Some Account of the Medical Profession in New Haven. By Francis Bacon, M.D., New Haven, Conn. 44 pages.

207. Two Successful Cases of Brain Surgery. By Charles B. Nancrede, M.D., Philadelphia. From the *Medical News*, November 24, 1888. 14 pages

208. Is the Electric Light Injurious to the Eyes? By George M. Gould, M.D., Philadelphia. From the *Medical News*, Dec. 8, 1888. 23 pages.

209. Exploratory Trephining and Puncture of the Brain almost to the Lateral Ventricle. By W. W. Keen, M.D., Philadelphia. From the *Medical News*, Dec. 1, 1888.

210. Preliminary Report of an Operation for the Formation of an Artificial Pupil through the Sclerotic Coat of the Eyeball. By George Strawbridge, M.D., Philadelphia. From the *Medical News*, Dec. 15, 1888. 12 pages.

211. Conditions Rendering Diagnosis Difficult in Pelvic and Abdominal Diseases. By T. B. Harvey, M.D., Indianapolis, Ind. 14 pages.

212. El Paso, Texas, as a Winter Health Resort. By W. M. Yandell, M.D., El Paso, Texas. 10 pages.

206. The history of the medical profession in any part of the United States, if well written, could not fail to be of interest; but that of the older sections of the country has a peculiar charm, because it takes the student back to the time in which our forefathers were laying the foundation for the superstructure which in our day extends so far and towers so high. In the pamphlet before us Dr. Bacon has brought together, in most attractive and entertaining shape, reminiscences of the early practice of medicine in and near New Haven, which have a much more than local interest. The work is done with a grace of style and a shrewdness of commentary which are characteristic of the family to which the author belongs.

207. In one of the cases which Dr. Nancrede reports he trephined the skull to find a bullet, the course of which he traced to the base of the skull but could not follow further; in the other he excised the thumb-centre for Jacksonian epilepsy. Both patients recovered. The description of these operations is both interesting and instructive, and the paper which contains it is a valuable contribution to the literature of surgery of the brain.

208. Dr. Gould, after a careful review of the evidence in regard to the effect of the electric light upon the eyes, answers the question of the title of his paper in the negative. More than this, he shows that the cases in which the electric light has proved injurious to the eyes are to be attributed to its improper use, and he urges the general adoption of electric lighting for all public halls. His pamphlet contains a valuable bibliography of the subject.

209. The literature of brain surgery bids fair soon to rival that of abdominal surgery; and Dr. Keen's contributions to it are always of great interest and

value. In the pamphlet before us he describes, with excellent illustrations, the history of a case of abnormal intracranial pressure, in which he trephined the skull, and punctured the brain, in the hope of giving vent to the fluid which caused the trouble. Unfortunately he failed to reach the fluid, although he came very near to it. His patient died, and the autopsy showed that Dr. Keen's exploratory puncture had come within a quarter of an inch of the fluid, which was contained in a distended left ventricle.

The experience of this case, added to the operator's general experience, leads him to propose tapping the ventricles of the brain as a definite surgical operation, and he describes the method by which he thinks this operation may be most safely performed. Such a proposal challenges the thoughtful attention of all surgeons and students of injuries and diseases of the brain, and Dr. Keen's pamphlet cannot fail to attract very wide spread notice.

210. Dr. Strawbridge makes an exceedingly ingenious suggestion for the treatment of incurable leucoma, and one which is likely to attract as much attention as Von Hippel's method of trephining the cornea. At the time of publishing his article he had made a number of successful experiments by his method upon the eyes of rabbits, and he had done two operations upon human eyes. Sufficient time had not elapsed in the latter cases to demonstrate what the ultimate result of the operations would be; and this result will be looked for with the deepest interest.

211. Dr. Harvey calls attention to the necessity for examining patients carefully in order to avoid the error of overlooking unconspicuous, but important disorders. The special field which he considers is that of the abdominal and pelvic viscera of women; but what he says has a still wider range of applicability.

212. Dr. Yandell has taken up the teaching of Dr. Denison, of Denver, and applied it to the case of El Paso, in such a way as to indicate that the latter is a very desirable place for the residence of persons affected or threatened with consumption. He claims that El Paso has, in common with southern New Mexico and southern Arizona the best Winter climate in the United States for consumptives and asthmatics, as well as persons suffering with other chronic pulmonary affections.

Literary Notes.

—The *Independent Practitioner*, a dental journal published in New York and Philadelphia, has changed its title to *The International Dental Journal.*

—The *Journal of the Respiratory Organs* is the name of a new magazine, edited by J. Mount Bleyer, M.D., and published by Napoléon Thompson, of New York. The first number is dated January, 1889, and contains 13 octavo pages of reading matter. It is to be issued on the fifteenth of each month; subscription price $1.00 a year.

—The American Biographical Publishing Co., Philadelphia, announces that a work on American Resorts, with notes upon their climate, by Bushrod W. James, A.M., M.D., with a translation from the German by Mr. S. Kauffman of those chapters of "Die Klimate der Erde," written by Dr. A. Woeikof, of St. Petersburg, Russia, that relate to North and South America and the islands and oceans contiguous thereto, is in press and will shortly appear.

Correspondence.

A Defense of Homœopathy.

To the Editor:

Sir: A few days ago, I was shown an editorial in the Reporter, Oct. 6, 1888, entitled "The Homœopathic State Medical Society of Pennsylvania." I am sorry it had not come to my notice earlier, as I should have had a reply in your hands long ere this.

Your reference to the fact that the Homœopathic State Medical Society of Pennsylvania had just concluded an interesting meeting in Philadelphia, and had displayed a fitness for the discussion of important medical questions which would hardly be expected by those who are not familiar with the advances made of late by those who bear this designation," is perfectly correct; but you err when you say that "the proceedings at this meeting were so like those of any 'regular' medical society that it is hard to discover any homœopathy in them at all."

You err, however, when you state that "the tenets of Hahnemann have come to occupy but a minor and subordinate position in their (*i. e.* the Homœopaths') thoughts and practice." I doubt if there was one in all the large gathering of members of our school at the session of the society who subordinated the Homœopathic principle in his thoughts or practice. Never have the laws of Hahnemann been so well understood, or so freed from the things that unfortunately since his day have somewhat hampered the growth and development of his system. The law of *similia similibus curantur* is upheld by our school no less vigorously to-day than formerly. But time and the progress of things have taught us wherein we were weak and needful of strength. The transactions of our societies are therefore more liberal. We are striving to give the principle of the *similars* its proper value, and to that end we investigate and court investigation. If our law of cure is universal in its application, our effort is to prove it; if it is not, still we aim to seek the truth and in the finding give it proper place. The old school is in need of an intelligent understanding of what we are really doing and of what we are really accomplishing. The time will surely come when the old school will believe as fully as we do, that the Homœopathic law is at least one of the laws of cure.

Is there not some mistake in the following

taken from your article: "The time will "yet come when . . . such men as made "the last meeting of the Pennsylvania State "Homœopathic Medical Society almost "undistinguishable from a similar meeting "of 'regular' physicians will not debar "themselves from association with all other "scientific medical men by holding fast to "a name which misrepresents them, and dis-"credits them in the opinion of men who "have no desire to be unjust or uncharita-"ble"?

Can you in all earnestness believe that such a time is near or ever likely to come? Is there a place in the old school of this city for the physician who has the courage of his convictions that Hahnemann demonstrated a principle in the laws of the similars? It is essential to the believers in Homœopathy that they class themselves together under the name which Hahnemann adopted; and this is true even for those who deny the *universality* of the Homœopathic law. What opportunity is afforded in the "regular" school for the study of the "similars"? Do you throw open to us your hospitals and your journals? Are we given fair-handed opportunity to demonstrate what we can do? When you allow us the freedom of action for which for years we have been pleading, then, and only then, can the two schools hope to commingle, and our title of "Homœopath" give place to that of plain "Doctor of Medicine."

I am glad that your article shows in some respects a spirit of fairness on your part. It is only by an unimpassioned, unprejudiced inquiry into the relative merits of the claims of the two rival schools that there can be entertained any hope of an ultimate solution of the problems of the hour.

Yours truly,

G. Maxwell Christine, M.D.

2043 N. Twelfth St., Philadelphia.

[This letter is given place in the Reporter because the writer has desired to have it published as a sort of justification of those who, he thinks, have been misrepresented in our columns. But, in doing so, attention is called to several points in it.

1. The writer cannot be aware of the belief and practice of many of his fellows in this city, or he would not venture the assertion that he doubts if there was one in the gathering spoken of who subordinated the homœopathic principle in his thoughts or practice.

2. He cannot be a careful reader of the journals of his own school if he believes that the law of similars is upheld as vigorously by his school to-day as formerly.

3. In reference to the appeal for a chance to work out homœopathic theories in regular hospitals: this is a most impracticable idea. There may be something more than coincidence in the fact that certain drugs produce in health symptoms similar to those of disease in which they may be administered with advantage; and this is a proper subject for unprejudiced investigation; but the claim that homœopathy, or any other "pathy" furnishes a universal law of treatment is condemned by all unbiassed scientific men. This condemnation is usually spoken of as if it applied only to homœopathy; but it applies equally to every exclusive dogma, whether it be homœopathy, or hydropathy, or electropathy, or vitapathy.

As asserted in our editorial, we believe the time will come when the rational men who bear the name of homœopath will drop this inappropriate and deceptive designation, and leave the title to those to whom it properly belongs—to the advantage of all concerned. It is not possible for assimilation to take place between such miscalled homœopaths, and those whose scientific methods they approve and imitate, until the former refuse to be called by a name which is practically false, and announce their adherence to those principles of reason which alone deserve the name of scientific. We know that this fact is appreciated by some who still permit themselves to be denominated homœopaths, and we hope that they will yet find occasion to declare publicly that what they believe of homœopathy is but a part of what experience teaches, and not what the real homœopath thinks it—an exclusive and universal law.]

Nasal Bougies.—A Correction.

To the Editor.

Sir: May I make a correction in the article on Nasal Bougies (Reporter, Feb. 2, p. 146), which you did me the honor to republish?

The strength of the nasal bougie is given as one-twentieth of a grain of atropine; it should be one-one hundred and twentieth of a grain of atropine.

Yours truly,

H. C. Wood, M.D.

Philadelphia, Feb. 4, 1889.

—Dr. Oliver Wendell Holmes has presented his medical library to the Boston Medical Library Association.

Notes and Comments.

Regulation of the Sale of Milk in Philadelphia.

The Sanitary Committee of the Board of Health of Philadelphia at its meeting, January 29, 1889, presented a petition to be submitted to the State Legislature with reference to a regulation applying to the sale of milk in Philadelphia. The petition is rather voluminous, and states that the Board of Health, recognizing the necessity of a strict supervision over the milk supply of the city, whereby the purity of a most important article of food shall be secured, petitions the Legislature to adopt such legislation as will best effect this object.

It suggested that in order to protect the public health a law be enacted which shall embrace a number of provisions contained in the petition. Among these suggestions are: That if any person or persons shall sell or exchange, or offer for sale or exchange, or have in his, her, or their premises, with intent to sell or exchange, milk to which water, ice, coloring matter, or any other foreign substance shall have been added, or milk from which the cream, or any part thereof, shall have been removed, or milk taken from a cow fed upon distillery-waste or any other substance tending to make her milk unwholesome, or milk taken from a sick or diseased cow, or milk exposed to infection or unhealthy exhalations, or not of standard quality, shall be guilty of a misdemeanor, and upon conviction shall be sentenced to pay a fine not exceeding $100 or be imprisoned not over six months, or both or either, at the discretion of the Court.

Evaporated or condensed milk shall contain 25 per centum or more of fat, and milk containing 12 per centum of milk solids shall be deemed of standard quality, and all other milk shall be deemed not of standard quality. This does not apply to buttermilk.

In cities of the first class the Director of Public Safety is directed to appoint an Inspector of Milk, with assistants, clerks, analysts, and collectors of samples. The latter are directed to take a fair sample of any milk offered for sale, and for such purpose may enter all places where milk is stored or kept for sale, and have access to all wagons, carts, or other vehicles used for the conveyance of milk and open any vessel or package containing milk for sale or exchange. Whenever an Inspector or Collector takes a sample of milk he is required to divide it into two parts and put each into a separate can or vessel and seal (it) in the presence of the owner or owners or their agents or employes from whom the sample was obtained. One part shall be offered to the owner or owners, agents or employes, and the other shall be retained and analyzed or tested. Unless the provisions of this section are complied with the result of the test shall not be received in evidence in any prosecution brought under the Act. If any person or persons shall hinder, obstruct, or interfere with any Inspector, or Collector of samples in his collections, or if any person or persons use or have any imitation of the Collector's seal, they shall be guilty of a misdemeanor, the punishment, on conviction, being the same as referred to above.

It shall be unlawful in any city after an Inspector has been appointed for any person to sell or exchange milk without a license. All applications for a license are required to be made in writing to the Inspector of the Milk for the city for which the license shall be desired, which application shall contain the location of the place or places and the number of vehicles for which licenses are desired. It also provides that, unless City Councils make other provisions, the sum of $10 shall be tendered for each place, $5 for each vehicle, for which a license is desired. After application has been made, the Inspector shall issue a certificate to the applicant showing whether the license is for a place or vehicle. These licenses shall expire on the 1st of May of each year, and the Inspector is required to keep a record of all the licenses granted. Cities of the first class are empowered to substitute for the license charges named any sum deemed expedient. In cases of removal of location a fee of 25 cents is to be charged for changing the certificate and records.

Licenses may be transferred upon personal application to the Inspector and the payment of the fee of 25 cents for the changes made on the records. In all cases the certificates of licenses must be displayed conspicuously. If any person not licensed shall sell or exchange milk, or if any person make a false statement in application for a license or transfer, or if the certificate be not conspicuously displayed, or if milk be sold from a vehicle not properly marked, such person or persons so offending shall be guilty of a misdemeanor. It will be the duty of the Inspectors to cause the arrest of any person against whom they have sufficient evidence.

All moneys received from licenses, charges, and fees are to be paid into the City Treasury and shall constitute a separate fund to be appropriated by Councils.—*Telegraph*, Jan. 29, 1889.

New Method of Illuminating Internal Organs.

The Vienna correspondent of the *Lancet*, Jan. 5, 1888, says that the well-known experiment for showing total reflection of light in a jet of water or in a glass rod has been made use of in Vienna by Dr. Roth and Professor Reuss in devising a new method of illuminating from outside some cavities of the body, such as the larynx and nose. The instrument used for this purpose is a well-polished (not blackened) glass rod, to one end of which a small electric incandescent glow lamp, like those used for electric breast pins, is attached. The light of the lamp is reflected equally through the whole glass rod to its other end, which is placed on the skin of the throat in the case of a laryngoscopical examination being required; then the interior of the larynx becomes illuminated sufficiently for laryngoscopy. If this luminous glass rod is applied to the sclerotic, the interior of the eyeball can be examined in the same way as by using an ophthalmoscope, the structure of the posterior parts of the vitreous body being very well seen and studied. As the glass rod remains cold, it can be employed in operative surgery to light the natural and artificial cavities.

Evil Effects Following the Administration of Sulphonal.

Dr. Schotten, of Cassel, reports a case of this kind in the *Therapeutische Monatshefte*, Dec., 1888. A woman 45 years old, a hemiplegic since her twentieth year as the result of chronic myelitis, was a victim of wakefulness. Schotten gave the patient sulphonal, three days in succession, in doses of fifteen and 45 grains. Under its influence she was affected with extreme prostration, headache, anorexia, and a bitter taste in the mouth. Four days later her body was covered with an eruption resembling measles; at the same time the other symptoms attributed to the sulphonal disappeared. The eruption was accompanied with a sensation as of burning and of heat in the skin, and lasted fifteen days.

A sister of the patient had presented a similar eruption following the use of antipyrin.—*Gazette Médicale de Paris*, Dec. 29, 1888.

Therapeutics of Iodol.

Prof. Dante Cervesato, of Padua, has communicated to *Lo Sperimentale*, September, 1888, his experiences with the therapeutic use of iodol in internal diseases. It was first tried in scrofulosis, in all forms of which it acted well. It was most active in the torpid form, especially in torpid, swollen lymph glands which had not yet suppurated —and not only in the peripheral glands but also in the bronchial and mesenteric. It was less favorable in its action upon scrofulosis of the mucous membranes, especially of the nose and ear. It has very little influence upon scrofulous dermatoses. It was employed internally in doses of seven and a half, fifteen, and twenty-two and a half grains in older children, and the treatment could be kept up without harm for two or three months uninterruptedly. Iodoform ointment (one part to fifteen of vaseline) and insufflations of iodoform were useful adjuncts. The iodol was well borne; not only did no digestive disturbances occur, but the digestion even improved. In diseases of the respiratory organs iodol was given in doses of fifteen to forty-five grains a day, in addition to inhalations with the following solution: one part of iodol is dissolved in five parts of warm absolute alcohol; to the filtered solution ten parts of glycerine (at 60°—70°) are added. Before the solution cools, ten parts of water are added with constant stirring. The iodol remains proportionately suspended for a long time. Four drachms of the emulsion are used for each inhalation, which is given two or three times a day. He has observed marked improvement in primary tuberculosis of the larynx. In acute and chronic catarrhal laryngitis, and in different forms of bronchitis, the results were brilliant. In tertiary syphilis it was employed with very favorable results. Two patients with extensive ulcers on the palate and pharynx recovered after the internal and local use of iodol for two months. Internally iodol was given in doses of fifteen to forty-five grains; the following solution was used locally:

Iodol	gr. xv
Alcohol	f ʒ iv
Glycerine	f ʒ viii

M.

In a case of tertiary syphilis with lesions of the liver and of the larynx, the internal use of iodol achieved wonders. No iodisin nor any other disagreeable accompanying symptoms whatsoever occurred in any of the cases.—*Wiener med. Presse*, Dec. 2, 1888.

The Doctor as a Civilizer.

The large part played by medical travelers and missionaries in the most remote and uncivilized parts of the world in attracting the affection of savage populations, and leading them in the path of civilization, is not the least glorious page of medical history, and would afford material for an interesting research. Mr. George Curzon, in his account this month of a *Visit to Bokhara the Noble*, gives a highly interesting sketch of Dr. Heyfelder, who was chief of the medical staff in Skobeleff's Turcoman campaign. "It would be hard to exaggerate the part which his manners and generosity have played in the pacification of this whilom haunt of fanaticism. As early as six in the morning people crowd into the Embassy to see him. Very often so childish is their faith that they do not ask for a prescription, but simply implore his touch. . . . A fat old Bey, he told me, came to him one day and said: 'Can you make me better? I suffer from eating four dinners a day.' 'Certainly,' said the doctor, 'eat three.' Thereupon the old gentleman became very angry, and retorted, 'How can I eat less when I am called upon to entertain venerable foreigners?' I asked the doctor whether it was out of benevolence that he continued to reside in Bokhara. 'Yes,' he replied, 'and as a pioneer of civilization.' "—*British Med. Journal*, Jan. 12, 1889.

Statistics of Operations on the Gall Bladder.

Dr. A. Depage, in the course of a paper upon Surgical Intervention in Biliary Lithiasis (*Journ. de Méd. Brux.*, 1888, No. 24), says that up to the present there have been 78 cholecystotomies performed. Of these operations, 6 were done according to the method of Spencer Wells, 72 with suture of the gall bladder to the abdominal wall. Of the first-named series, 3 patients died from acute peritonitis, in 1 cured case there was recurrence, and 2 patients were completely cured. Of the second series there were 11 deaths, 5 from hemorrhage and collapse, 2 from biliary retention, 2 from effusion of bile into the peritoneum, and 2 from undetermined cause; there were also 4 deaths from secondary complications. Amongst the "cures" are 24 cases of biliary fistula, some permanent. The number of cholecystectomies has been 22, with 2 deaths from obstruction of the bile duct, and 1 after recovery from the operation from a cause independent of biliary lithiasis. Thus in cholecystotomy with suture of the gall bladder, and its return free into the abdominal cavity, a mortality of 50 per cent. resulted; in cholecystotomy with suture of the bladder to the parietes, 15.27 per cent.; and in cholecystectomy, 9.99 per cent.; and as the last-named figure comprises the two cases of permanent occlusion of the common bile duct, the result, if they be excluded, is to enhance greatly the position of cholecystectomy as an operation to be preferred to cholecystotomy.—*Lancet*, Jan. 12, 1889.

Frequency of Diseases of the Nose and Throat.

Dr. W. Franklin Chappell, Attending Physician to the Chest and Throat Department, Presbyterian Hospital, New York, has undertaken to ascertain the frequency of diseases of the throat and nose. In his paper, published in the *American Journal of Med. Sciences*, Feb., 1889, he gives some interesting details of his examination of the noses and throats of two thousand children. Nine hundred and fifty-five of these were from the New York Juvenile Asylum, six hundred and forty-five from the Grammar School No. 49, and two hundred from the Half Orphan Asylum in East 10th Street, and the remaining number from various sources.

In the entire number the following abnormal conditions were found: Adenoid growths, 60; enlarged tonsils, 270; deviated septa, 330; spurs on septa, 150; hypertrophy of inferior turbinated bodies, 260; hypertrophy of middle turbinated bodies, 161. This shows that 1231 were suffering from some anatomical abnormality, and usually with its accompanying symptoms of respiratory obstruction and catarrh.

After an analysis of these statistics, he expresses the opinion that enlarged tonsils and adenoid growths are the only anatomical abnormalities that can be classed as belonging to very early life. The other abnormal conditions are acquired usually after the age of six years, increasing rapidly with each succeeding year until puberty. All social classes are liable to them in about equal proportions, and at the same age. Males, he says, suffer more frequently than females, probably owing to greater exposure to the causes which produce catarrhal congestion and inflammation. In glandular organs it is but a step from congestion to hyperplasia, and an increased afflux of blood being once established, a slight irritation will serve to keep it up, and hypertrophy is the necessary result.

Hospitals for Contagious Diseases in Tennessee.

In his report to the State Board of Health of Tennessee, Jan. 8, 1889, the Secretary, Dr. J. B. Lindsley, spoke as follows:

"As to yellow fever we must not conceal the fact that the outlook is ominous. All sanitarians in the Southern States familiar with the past are very uneasy about the coming summer. There is but one way open to us, namely, to look the possibilities fairly in the face and be ready for any emergency.

"In this connection a local matter of great importance should not be overlooked. The four cities—Memphis, Nashville, Chattanooga, and Knoxville—each centres of great travel and traffic, visited by thousands annually, not only from Tennessee, but from States near and far, with large floating populations, should, without delay, provide suitable accommodations for the care and treatment of persons suffering from communicable diseases—ordinarily termed contagious or infectious. Such hospitals should be isolated, but not at too inconvenient a distance. They need not be large, but should be always equipped and ready for use, and competent physicians and nurses constantly retained for service. No one can tell when such hospitals will be wanted. These four cities are already noted and populous, rapidly growing also, and are without excuse for not making such provision for the stranger within their gates or their own people, many in number, who cannot be well cared for at home."—*Tennessee State Board of Health Bulletin*, Jan. 15, 1889.

What are we to Know?

Canon Isaac Taylor, in an address on "Literature and Culture," published in the *Church Worker*, has given some advice which, with some obvious modifications, doctors and medical students would do well to lay to heart. He said: "It is impossible for any one man to know everything—*omne scibile*. Two hundred years ago it was possible; but now the domain of knowledge has been so vastly extended that it is impossible. In these days, to be distinguished, a man must be a specialist—he must devote himself to some department of knowledge. It is impossible, for instance, that the same man can be at once a great historian and a great chemist. It was said of Whewell, that while science was his forte, omniscience was his foible. Because he knew so much, he thought he could know everything; and so, if you strive after universal knowledge, what you will attain will not be science, but sciolism. Strive after universal knowledge, and you will become a universal smatterer. On the other hand, the mere specialist tends to become a narrow pedant. How shall we avoid these opposite dangers—sciolism and pedantry? I think the best rule for a young man to set before him in his studies is, to resolve to know something of everything, and everything of something. To know everything of something is to choose some one branch of science for your specialty, and to learn everything that can be learned about it; this will give you accuracy and precision. To become 'an authority,' as it is called, on some one subject, however small—on butterflies, birds' eggs, or even on postage stamps—is better than nothing. Still better is it to take some department of history, or of geology, or of philology, and master it thoroughly. But this is not enough. You will thus learn to be accurate, exhaustive; but you will be narrow. You must not only know everything of something; but, to gain breadth of mind, you should also resolve to know something of everything. Strive to take a general interest in every department of human knowledge. Strive to know enough of every science to enable you to listen intelligently to any great specialist you may chance to meet, and to read with profit any great epoch-making book that may appear. Such knowledge cannot be deep; but such an imperfect knowledge adds immensely to the intellectual pleasures within your reach, and will constantly throw light on that one branch of knowledge which you have specially made your own."—*Bristol Medico-Chirurgical Journal*, Dec., 1888.

Naval Board of Medical Examiners.

The Board of medical officers is now convened at Philadelphia for the examination of applicants for appointment as assistant surgeons in the navy, and will remain until March 31; it has been ordered to meet at the Naval Hospital, Brooklyn, April 1, and to remain there until the following October. The change is made to enable students at the New York and Brooklyn hospitals to be examined by the Board without the expense of leaving their homes. There are fourteen vacancies in the grade of Assistant Surgeon. Further information may be obtained by addressing the President of the Examining Board.

NEWS.

—Small-pox of a malignant type is reported to be increasing in Nanticoke, Pa.

—Dr. Heinrich A. Pagenstecher, the eminent zoologist, has recently died at Hamburg.

—Dr. John A. Fisher died in New Orleans Jan. 15. He was a native of Lebanon, Pa.

—Dr. W. R. D. Blackwood was elected President of the Anti-Vivisection Society at its recent meeting Jan. 28, 1889.

—Dr. Charles Bliss died in New York City Jan. 23. He was graduated from the Berkshire Medical College in 1865.

—Prof. Ziegler of Tübingen has been invited to take to Professorship of Pathological Anatomy in the University of Freiburg.

—Dr. E. A. Neely, who has just withdrawn from the editorial staff of the *Memphis Medical Monthly*, was married at Memphis Jan. 23.

—Dr. John Underhill died in Cincinnati, Ohio, Jan. 28, from the effects of cocaine, to which he is said to have become habituated through experimentation.

—Typhoid fever is epidemic at Lake View, Cook county, Illinois. The *Journal of the Amer. Med. Association*, Feb. 2, says that there are now nearly fifty cases of the disease.

—The Eighth German Congress for Internal Medicine will be held in Wiesbaden from April 15 to April 18, 1889, under the presidency of Prof. von Liebermeister, of Tübingen.

—Dr. William A. Edwards has established a private Hospital at San Diego, Southern California. The nursing will be conducted by graduates of the Philadelphia Hospital Training School.

—A disease presenting some peculiar symptoms has made its appearance in Webster county, Kentucky. It seems to be traceable to impure water and poisoned atmosphere, and is said to be rapidly fatal.

—Another doctor has been beaten by White Caps who have committed some outrages at North Manchester, Indiana. Dr. W. H. Clair was recently assaulted on the principal street of the place and ordered to leave town. He was beaten over the head and shoulders with clubs, and then shot at, one of the bullets inflicting a painful wound.

HUMOR.

A FOND MOTHER of a smart boy was making a lot of nice preserves one day, and as she sealed them up she labelled them thus: "Gooseberry jam put up by Mrs. Mason." Johnnie soon discovered the shelf on which they were deposited, and fell to work. Having emptied one of the jars, he took his school pencil and wrote underneath the label: "Put down by Johnnie Mason."—*Am. Druggist.*

"MAY I LOOK through your waste-basket?" inquired a young man, entering timidly. "Certainly," said the editor. "What do you want to find?" "A little poem on 'Mortality' that I sent in yesterday." "My dear sir, that poem was accepted and will appear to-morrow. I will draw you a check for $25, and I assure you—" But he spoke to lifeless ears. The young man had fallen to the floor. The shock had killed him.

A DERMATOLOGIST, being seated by a lady unknown to him, at dinner, when conversation lagged, remarked interestedly, "Have you noticed the spots on that man's face across the table?" To which she indignantly replied, "Excuse me, sir; that is my husband!" The skin man, being a Briton, and so never to be crushed by circumstances, most enthusiastically said: "Ah! that *is* fortunate; then *you* can tell me whether he is spotted like that all over, *cawn't* you?"

OBITUARY.

MARTIN L. WEAVER, M.D.

Dr. Martin L. Weaver died at his residence in Germantown, Feb. 1. He was born in Germantown about eighty-four years ago. His grandfather, Martin Webber, came to America about 1714.

Dr. Weaver was graduated from the University of Pennsylvania in 1829, receiving his preliminary education at Princeton College. At one time he contemplated entering the ministry of the Presbyterian Church, and took a theological course at Carlisle. He never took a regular charge, but employed the greater portion of his time as co-executor of his father's estate.

Dr. Weaver came into prominence in the newspapers several years ago through the trouble between his daughter and his second wife. Efforts were made to have him adjudged insane and his marriage set aside, but the Courts decided in his favor.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

THERE IS A PEPSIN

WHICH IS UNIFORMLY ACTIVE, PERMANENT, AND RELIABLE,

IT IS "FAIRCHILD'S."

This Pepsin will not spoil, will not become soft and sticky in the vial, even if left long uncorked.

Fairchild's Pepsin will not "gum up" if dispensed in powders, plain, or with the drugs usually combined with pepsin.

Fairchild's is not a partial peptone, and has none of the well-known characteristics of peptone.

Fairchild's is the pioneer pepsin, it showed the way. It "got there" early.

Its activity has never been exaggerated.

All this time, whilst other manufacturers were still offering the high-dilution saccharated and amylated article, Fairchild's Pepsin was steadily making its way on its merit. Now, no one ventures to ask a hearing for these *placebo-pepsins*.

When physicians now prescribe "pepsin" they mean pepsin—not milk sugar, and pepsin.

All these years, Fairchild's Pepsin was always and everywhere found to do just what was claimed for it—in spite of the attitude, genuine or assumed, which held that all "claims" about pepsin must be taken with a liberal discount.

Every *bona fide* test demonstrated its reliability.

We have never found it necessary to explain or excuse any deficiency or inaction as due to "deteriorated" specimens.

Fairchild's will not disappoint the prescriber under any condition proper for pepsin.

With Such a Record Fairchild's Pepsin is a good one to stand by

FAIRCHILD BROS. & FOSTER,
82 and 84 Fulton St., New York.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

CLINICAL LECTURE.

RHEUMATISM WITH ARTICULAR, CEREBRAL AND VISCERAL SYMPTOMS.[1]

BY PROFESSOR M. PETER,
PARIS, FRANCE.

(Reported specially for the MEDICAL AND SURGICAL REPORTER.)

Gentlemen: We saw for the first time, this morning, a patient in the Laennec ward, who struck me as furnishing a good lesson for you. In examining him I was first of all taken aback with the lamentable aspect of his face and the deplorable state of his pulse, which is irregular and almost imperceptible. The disease is what I call "*mad rheumatism.*" The patient is pale, his nose is pinched, and his aspect is not that of a person with a febrile malady, but rather that of one profoundly depressed. The tongue is dry, the abdomen swollen, and there was an involuntary stool this morning; so that those who noticed these symptoms will say, "It's a typhoid fever case;" but it is not. I will explain why.

The patient is lying in the dorsal decubitis, it is true, but when an attempt is made to move his arm he has an intense pain in the scapulo-humeral articulation. The disease is rheumatism. But, you will say, a singular rheumatism to be accompanied with swollen abdomen, involuntary stools and irregular heart action. Talk to him, however, and you will find out that he is a market porter, and that he has been in the habit of "drinking without counting." You know the habits of these men—always a drink after each basket they carry, so that they take as much as four or five quarts of wine a day. The patient is then an alcoholic; he says it is part of his profession. It will always be found that disease in an alcoholic patient will differ from the usual type. The patient says that some seven or eight years ago he had articular rheumatism, for which he was treated in this same hospital with salicylate of soda, and that he recovered. It does

[1] Delivered at the Hospital Necker, Paris.

not appear that he had endocarditis afterward, with a mitral insufficiency. I say this because we cannot tell, in organs that have been drenched with alcohol for eight years, whether there was a lesion of that kind or not. As to his present trouble, he says that fifteen or twenty days ago he was taken with pulmonary congestion, for which leeches were applied over the right lower thoracic region. The redness still persists there, which shows the bad state of his skin, which consists in a tendency to lymphangitis of a sub-inflammatory order; it also shows that his tissues are just as weak as his other organs. It seems that he was cured of his pulmonary congestion when he commenced to have delirium, and his doctor said: "I don't understand this; he is delirious and yet better of the pulmonary trouble." And now fever lights up again, and he has pains in all his joints. In a word, he had rheumatism in the first place, and it is probable that his congestion was rheumatic. He is a rheumatic subject, as these visceral localizations indicate.

When asked to show his tongue, he simply turns it as he would a ball, with the greatest difficulty, and puts out the tip, which is dry and of a typhoid look. The patient says he cannot put it out further. If the finger is pressed below the temporo-maxillary articulation, it will be noticed that he says nothing; but if it is pressed on the articulation itself, he screams with pain, so that he has a bi-lateral temporo-maxillary arthritis. This is rare in rheumatism; but as I led you to expect, all is unusual in such cases. Has he then acute articular rheumatism? No; he has what I call "*fievre rhumatismale typhoidique*," called also rheumatic fever. It cannot be doubted that he had visceral rheumatism. From the start his congestion was rheumatism, his delirium was cerebral rheumatism. But this rheumatism shows itself not only in the brain, but also in the heart symptoms; there is no rhythm in the heart beat, and we never find that endocarditis produces arhythmia. It determines mitral insufficiency, by default of tension or by alteration of the valvular surfaces; it can only produce trouble in the circulation by a reflux of the blood—a physical fact that shows a physical lesion. But a rhythmic disorder of the pulse such as this, is only seen when the heart-muscle itself is altered. There is present in this case an alteration of the innervation of the heart, analogous to the trouble in his intelligence, which came from a like disorder of the brain. The patient has, therefore, a rheumatism of the heart, not endo- but myocardial, and perhaps also neuritis by fluxion on the nerves of the cardiac plexus.

Is this all he has? No; because the swollen abdomen and the involuntary stools show that there is also an intestinal, visceral rheumatism. The digestive tube is in somewhat the same state that it is in typhoid fever; that is to say, there is a paralysis of the muscular tunic of the intestines, which causes a swelling of the abdomen, and a fluxion of the glands, giving rise to the diarrhœa; but there are no lesions of Peyer's patches.

I must try now to give you an idea as to what ordinary rheumatism is, and what cerebral rheumatism is like. More than half a century ago, Bouillaud wrote a treatise on "Acute Articular Rheumatism," and he made it out a prototype of inflammation; but notice that he called it acute articular rheumatism, and not rheumatic fever. He thought it was an inflammatory malady of the articulations, and he called valular endocarditis an arthritis, as though the valves were articulations and the trouble was the same; so that for Bouillaud it was an inflammation that was pathologically localized in articulations for the body, and on the valves when the heart was affected; but all this is an absolute error, for in an autopsy of a case of acute articular rheumatism as given by Bouillaud, it will be noticed that he tries to prove that the troubled aspect of the heart, or rather of the pericardium, is owing to inflammation; but both the endocardium and the articular surfaces are intact; there are not even any signs of vascularity of the tissues. In fact, there are none of the lesions found in arthritis, and we are obliged to say it is not an inflammation of the articulations. It is a fluxion which had already left the articulation; and just because it is a simple fluxion, there is produced in these cases a wandering of its manifestations; during several days it will appear at many different points, but a real arthritis never does this. It is, therefore, a malady with a flux from the natural tissues, which appears at different articulations, and may also appear on the endocardium, the brain and the intestines, as it has done in this case. Remember this fundamental fact: acute rheumatism is a general malady with fever. It is a fever; so we shall say, acute rheumatism with fever. It is articular as a rule; but it may not be so, and in our case there was delirium, which the doctor did not understand. Do you know what is found at the autopsy of a person who

dies of cerebral rheumatism? Why, nothing; no more than is found in the articulations in acute rheumatism; because, as I said before, it is not a cerebritis but a simple fluxion, which goes away after death. A little cerebro-spinal liquid has been found in a few cases, owing to an intense flux of the meninges. But it is a very serious affair to have a flux in the brain, much more so than to have one in the articulations; the last gives great pain, but is rarely mortal; while the first is often fatal, especially after delirium.

I say that rheumatism is a malady which strikes wildly at different organs; but why was the brain attacked in our patient's case? Simply because he, like many others who get this trouble, was a weakened man. We most often see attacks of cerebral rheumatism in private hospitals, because they are the homes of patients who have met with bad fortune, or who have wasted their health and abused life in many ways, and end by going to such places for care. Many of these people suffer from cerebral rheumatism. Or it may be that the patient at such places is a ruined banker, or perhaps a writer, or a poet; and in such persons the brain is the part of less resistance. I won't say such patients have poor brains, although I may think it as regards poets; but they are all persons who have used up what brain power they had, so that the brain is in a state of hyperemia, and in a condition predisposing to cerebral rheumatism. Vigla, who wrote a work on this subject, was influenced by the reigning ideas of the time, and thought the affection was an inflammation; but in searching for the lesions Vigla, with scientific sincerity, was compelled to say that he could not see any; he was therefore reduced to making only a clinical description of the disease. But to return to our patient. The large quantity of alcohol that this man put into his brain easily accounts for his having cerebral rheumatism. The brain was a weak point with him, and he had so badly treated the whole of his organism that the rheumatism quickly became grave, and attacked the brain, the myocardium, and the intestines. It is a serious matter to have these organs attacked in such a manner.

Here I am obliged to take up a question of doctrine. A form of rheumatism has been described called infectious; which is distinguished from acute general rheumatism, and in particular from visceral rheumatism. This form is born of the microbe doctrine and is supposed to be engendered by a micro-organism, and to differ from another form called suppurative, which is engendered by a special micro-organism called after Heront. So that in these modern days, we have the frank acute form of rheumatism, or articular, which is the prototype of rheumatic fever; then we have a visceral rheumatism, which strikes at certain viscera; and cerebral rheumatism, although this is the same as the last; we have also the so-called suppurative form; next typhoid rheumatism, as in our patient, and lastly, infectious rheumatism. Is this last infectious on account of some micro-organism? No. I do not think so. It is infectious because of the bad state of the organism through some of the causes I have given, which produce the suppuration in an articulation, or the typhoid state. In the case of our patient, it was simply the hard work and harder drinking which depressed his organization so that he was left open to these maladies. I saw him for the first time this morning a little while before this lesson which I improvised for you at once, as his case teaches us an important practical matter in therapeutics. Besides, he may die and you will see my statements borne out by the autopsy, and you will know what to think of visceral rheumatism, as well as of the so-called infectious form.

What shall we do for him? Do *not* give him salicylate of soda. That would only make him go into a delirium again; perhaps the flux would be displaced and rush to one spot. His temperature was 102.2° F. yesterday, and this morning it is 100.4°, so that fever exists. Be careful in such a case not to give salycilates, as they may provoke cerebral symptoms which cannot be controlled, and the patient may die of cerebral trouble. What then shall be done? Give him Todd's potion (which is only one and a half fluid ounces of Cognac in four fluid ounces of water or other vehicle); then give thirty grains of watery extract of cinchona, just as though he was a patient with typhoid fever. Keep up his strength with good food, let him have soup and milk, and do not keep wine from him. Drunkards must never be deprived of wine, but it must be given with care. Then give sulphate of quinine, which does not act as the salicylates do, as it sustains nervous force, as coffee does. I should be disposed to give him also a hypodermic injection of caffeine. I should give only seven and a half grains a day of the quinine, enough to keep up nerve strength, and yet not cause congestion of the brain. You see I act

with care in this case. Then to night, if he is as weak as he appears this morning, I should give a hypodermic injection of one-sixth grain of caffeine; and this is all I would do. But if he become delirious, then I should not hesitate to put six wet cups on the cervical region, or two leeches behind each mastoid process, to attempt to take away the congestion; because his life would be in danger.

We are far from theory here; we do not give this man who has rheumatism salicylate of soda, the remedy that is best adapted to that trouble, because he is menaced with a cerebral affection. This is how you should learn pathology; not as you do your catechism, but by seeing the patients. You will then find out that your books on therapeutics do not contain all the truths necessary to practise medicine.

COMMUNICATIONS.

ABLATION OF TONSILS WHEN SMALLER THAN NATURAL.

BY GEORGE TROUP MAXWELL, M.D.,
JACKSONVILLE, FLORIDA.

Excission of the tonsils, when by increased size they cause danger or discomfort, is a common operation; but the removal of them, when from disease they become smaller than is natural, is an operation which, according to my information, has neither been performed nor advised by others. Nor, so far as my knowledge extends, has attention been directed to the pathological action which causes the reduction in the volume of the tonsils.

Although enlargement of a tonsil may be properly regarded as a hypertrophy, the result of excessive nutrition, it cannot be said with exactness that diminution of size is in all cases, if in any, due to the opposite condition, known as atrophy. Indeed, decrease in the dimensions of a tonsil is not usually due to failure of nutrition, but to destructive, suppurative inflammation.

The tonsils, it will be remembered, are not single glands, but are congeries of minute glands or follicles, bound into almond-shaped masses by connective tissue. With this anatomical fact borne in mind, it may be readily understood that the condition found in the single, isolated follicles of the pharynx, especially those of its posterior wall, in chronic follicular pharyngitis, may possibly exist in few or many of the follicles constituting the tonsils. This is, indeed, what frequently happens. A very common, if not an invariable, concomitant of that inflamed condition of the isolated pharyngeal follicles, which has given its name to the disease, is a slow but progressive destructive inflammation of the tonsils—one or both. Indeed, during the last thirty years I have found chronic suppurative inflammation of the tonsils, with loss of substance, associated with follicular pharyngitis so often, as to induce the belief that it is probably a very important factor in the etiology of that disease. I believe that chronic suppurative inflammation of the tonsil is the *causa causans* of follicular pharyngitis.

All are familiar with the phenomena of acute tonsillitis. The great distress caused by swelling and pain compels attention. But few if any have given thought and care to the organs when undergoing slow destructive inflammation. This is due to the almost complete freedom from pain located in the tonsils, to their decrease in size, which causes them to be overlooked upon inspection, and to the extension of inflammation to more conspicuous adjacent parts. The diffused redness, swelling and marked inflammatory action in the neighboring isolated follicles attract attention upon even a casual inspection, whilst the delinquent, painless, shrunken tonsil, partly hidden by the anterior pillar of the fauces, escapes notice. Not unfrequently the patient not having experienced pain or discomfort in the tonsil, is slow to credit the assertion that that organ is probably chiefly responsible for his "sore throat." In some cases nothing short of a demonstration, easily made, will convince patients that the charge against the tonsil is founded in fact. The explanation of the painlessness of the diseased tonsil, upon which the incredulity of patients is based, is that pus escapes with every act of deglutition, especially of solid food, through natural and abnormal openings; and there is consequently no distension of the tissues. Thus nature and disease provide ways of ready egress for pus from organs poorly supplied with nerves of sensation.

In examining patients suffering with follicular pharyngitis it is my habit gently to press the tonsils with a forefinger. If there is pus, which is more likely to be present several hours after meals, it will be seen escaping from minute orifices, and may be

caught upon the end of the finger. I have often demonstrated in this way, for the satisfaction of patients, the real seat of trouble. This done, there is rarely opposition to operative procedure.

Applications to the mucous membrane covering the tonsils, in the condition described, are absolutely profitless. They are, on the contrary, often hurtful. They do no good, because they do not reach the diseased tissues. They sometimes do harm, because by their irritating properties they cause swelling of the mucous membrane, and consequent temporary occlusion of the vents. Pus is thereby retained, and pain from distension results.

My method of operating is first to anesthetize the parts with cocaine, seize the mucous membrane covering the tonsil with a double tenaculum (Green's), and, with Green's probe-pointed long-handled bistoury, remove the membrane. Then the pyogenic tissues are exposed to the direct application of a strong solution of the crystals of nitrate of silver, four grains to one fluid ounce. When the wound thus made and treated heals, healthy tonsils remain; and usually the follicular pharyngitis is cured.

The principle of this operation is the same as that recommended by Solis-Cohen in the treatment of intractable, inflamed, isolated follicles, by splitting them with a knife before making application of nitrate of silver.

Thirty years ago I performed the operation I have described upon a man who had follicular pharyngitis, who, every winter, for ten successive years, suffered with one or more attacks of acute tonsillitis. He is still living, and has ever since enjoyed uninterrupted exemption from follicular pharyngitis, or acute tonsilitis. I could report hundreds of similar results were it necessary.

—Dr. Kruss, a chemist of Munich, Germany, is said to have succeeded in decomposing cobalt and nickel, both of which have hitherto been supposed to be elementary substances.

—The Sanitary Superintendent of New York City, says the *N. Y. Med. Journal*, Feb. 2, has reported to the Health Board that water contaminated with sewage is being used in some instances in the manufacture of carbonated waters. Physicians should bear in mind the possibility of such contamination when prescribing artificial carbonated waters.

RETAINED PLACENTA DUE TO SPASMODIC CONTRACTION OF THE UTERUS.

BY J. B. CARRELL, M.D.,
HATBORO, PA.

At 6 P.M., August 4, I was called by a neighboring physician, a man of much skill and experience in obstetrics, to assist in the removal of an adherent placenta.

The patient was a primipara of fine physique, and had given birth to her child at 9 A.M. of the same day. There was nothing unusual about the case, except the violence of the expulsive pains; the last pain forcing the child unaided entirely from the mother.

Unfortunately, in this case a dose of ergot was given and the delivery of the placenta not at once effected. Pain not coming on, the doctor attempted to deliver, and, not succeeding, concluded to wait. After an hour, he was unable to introduce his hand, on account of the powerful contraction of the uterus. There being no hemorrhage, he waited until 5 P.M., and then, finding no relaxation, sent for me to assist him. In my practice I had, by the free use of chloroform and perseverance, overcome several cases in which the womb was strongly contracted, and fully expected to overcome this one. However, I was much surprised after chloroforming the patient to the surgical degree, to find I could not introduce even the index finger through the strongly contracted os. Our efforts being unavailing, we concluded to wait until the next morning. Meeting again, we found the same condition as on the previous evening, and again decided to wait until 6 P.M. The os was well smeared with belladonna ointment and free doses of Hoffman's anodyne and opium given. At 6 P.M., we found the patient under a high state of excitement, temperature 104°, pulse 120, and a fetid discharge from the vagina. The uterus was still firmly contracted. After thoroughly anæsthetizing the patient, my friend attempted to pass his hand, while I steadied the uterus with both of mine. His hand becoming tired out, he took my place and I his. After ten or more minutes of persistent effort, I succeeded in passing my index finger, then the second, and finally the entire hand. Passing it up along the left surface of the womb, I found the placenta firmly adherent at the fundus, and with much effort peeled it off. Immediately, the womb contracted and forced both hand and placenta from the cavity. The vagina was

cleansed with an antiseptic solution, and from then on no difficulty was experienced.

This was certainly a remarkable case, and I have not read of or met its like. In cases in which the placenta is retained, it is usual for the uterus to relax in the course of a few hours, or, under the influence of an anæsthetic, it is possible by perseverance to succeed in passing the hand into the uterus. Although each of us was strong and determined, it was absolutely impossible for either to pass a hand. The uterus remained firmly contracted for thirty-three hours after delivery of the child, and then only by the most determined effort was it possible to succeed in passing the hand.

REPLACEMENT OF THE BUTTON OF BONE AFTER TREPHINING: WITH A SUCCESSFUL CASE.[1]

BY WILLIAM R. BALLOU, M.D.,
NEW YORK,
LATE HOUSE SURGEON, BELLEVUE HOSPITAL;
ATTENDING SURGEON OUT-PATIENT
DEP'T, BELLEVUE HOSPITAL.

In these days of exact and antiseptic surgery, recoveries after the operation of trephining for compound depressed fractures of the skull are sufficiently common not to warrant one's taking much time or space in their discussion. There is, however, one feature in the case I present this evening, somewhat out of the usual course, and for this reason I invite your attention to it.

The patient, a groom by occupation, while harnessing a horse, August 9, 1888, was kicked in the head by the animal. He was brought to the Hospital, and on admission was semi-unconscious and rambling and delirious in his speech.

A scalp-wound was found over the upper central portion of the right parietal bone, which led down to a depressed fracture of the skull.

Trephining and removal of the depressed portions was done under the most thorough antisepsis, the details of which I need not describe. The button of bone removed by the trephine was found to be healthy, and not contused, and it was immediately placed in a warm solution of mercuric bichloride (1-2000) until elevation of the depressed bone—which involved an area of one and one-half inches by three-fourths inch—was effected.

The button was then replaced, the periosteum carefully sewed over it, deep and superficial drainage-tubes were introduced, and the incisions in the skin were closed. The patient rallied well from the anæsthetic and had absolutely no unfavorable symptoms after the operation. On the fourth day, the drainage-tubes were removed, and the wound was found healthy. On the seventh day, there was a slight elevation of temperature; the edges of the incision, being raised at one point, were opened, and a small amount of purulent serum was evacuated.

The wound healed rapidly, and, on the eighteenth day, the patient was discharged. He has since reported regularly at my office. The wound has entirely healed, and the button has united to the rest of the bone. The man is in perfect health, and has pursued his vocation as groom for several months.

The points of interest in this case briefly summed up are: (1) that healthy bone may be replaced if the pericranium be sewed over it and the fragment be kept in a perfectly aseptic condition from the moment of its removal; and (2) that meningitis will not occur if all sharp spicules are removed and thorough antisepsis be carried out.

I would not recommend replacement of the button of bone in all cases, though Macewen, of Glasgow, and Barker, of the University Hospital, in London, have gone so far as to divide the bone into small fragments, which were placed on the dura, covered with the periosteum, and left as centres for ossification.

I have reports of six cases in which this procedure was resorted to, with two successes and four failures.

In one of the failures, meningitis is said to have developed.

In two cases, the buttons underwent necrosis and were removed within a few weeks. In one of these cases, the trephining was done for epilepsy, resulting from an old fracture of the skull; in the other, for a depressed pistol-shot fracture.

In both these cases, the bone was undoubtedly of low vitality. In such cases, replacement should not be attempted. In two of the three remaining cases, the operation was performed for old head injuries. In one case, the attempted replantation of the bone was successful; in the other it was not.

The sixth case is the one you have seen this evening.

The case I have just described occurred during the service of Dr. W. F. Fluhrer, with whose kind permission I report it.

No. 236 East Thirty-first Street.

[1] A paper read at the meeting of the Alumni of Bellevue Hospital, New York, Feb. 6, 1889.

BEDFORD SPRINGS AS A HEALTH RESORT.

BY H. B. RUNNALLS, M.R.C.S., L.S.A. ENG.,
BEDFORD SPRINGS, PA.

So much has already been written regarding mineral waters and climatology, that it is with some amount of diffidence that I add one more article to this, as yet, little understood subject. I doubt whether I should have done so now, but being acquainted with the various Spas in England, and on the European Continent, I was so struck with the many advantages of, and the general superiority of the Bedford Springs, although a much less known health resort, that I felt it would be more or less a boon to the profession, if I laid before them a few facts respecting this place.

In these days of mental strain and struggle for existence, the relationship between mind and body is only too often witnessed by the city physician, and how futile our attempts are to bring about a healthy equilibrium in such cases by the aid of medicine alone is too well known to all of us. The morbid conditions resulting from an unbalanced nervous system are indefinite, and we are only acquainted with the grosser symptoms accruing from a disordered state of the digestive system, which in our larger centres of population displays itself as gout, diabetes and the various kinds of kidney trouble; and in older countries, where the struggle for existence is more keen, pessimism and a distaste for life generally may be added. Shakespeare recognized the relationship between mind and body when he asks, "Can'st thou minister to a mind diseased?"; and we all know the difficulty of solving that problem. Perhaps no class of men more thoroughly appreciate and derive more benefit from a change of air and scene than physicians. To be hastened away from the worries and troubles of a seething mass of humanity, to the country town or hill-side village, where the air is pure and laden only with life supporting properties, makes life once more a joy, so that one does not ask himself now whether life is worth living.

Having had personally a considerable amount of experience in hospital surgery in London and also in the country I have been struck with the vast difference in the process of repair. The ruddy cheeks and sturdy limbs of the country-raised child, and the leaden complexion and emaciated condition of those born and bred in cities and large towns prove conclusively that pure air and good water are very important factors in the healthy growth of the human body, and valuable adjuncts or rather absolutely necessary aids when it is wished to repair a constitution broken down from disease or mental strain.

To appreciate thoroughly the advantages of pure air and pure water one should have lived in England during the last ten or fifteen years, during which time a revolution has taken place in the sanitary condition of houses and towns. When every house had its cess-pit and well of drinking water, with badly ventilated rooms, typhoid, typhus, diphtheria and many other of the diseases resulting from such causes, were rampant and numbered their victims by thousands every year; but now with uncontaminated water supply and the abolition of the cess-pool, these diseases have almost disappeared, and are considered preventable diseases, and sanitary authorities are liable to be sued for damages if these diseases arise within their precincts. One need but go to those countries where cholera and yellow fever produce their ravages, to understand the reason why these disease germs show such a decided predilection for those countries. The same causes though in a less degree are present in all large centres of population, and especially in low-lying lands, or where towns are encompassed by hills, thus preventing a free circulation of air, and the substitution of healthy atmosphere, for that impregnated with the exhalations of thousands of people with the odor arising from decaying animal and vegetable matter and with the fine particles of dust and soot arising from so many fires.

These causes to a great extent are responsible for the puny and ill-developed children; for the languor, lassitude, loss of appetite, sleeplessness, nervous irritability and other symptoms showing only too plainly the deficient supply of oxygen. All these cases defy medicinal treatment, but it is surprising to see how quickly these symptoms disappear after a short sojourn in an unvitiated atmosphere. To the poor these valuable aids toward recovery as a rule are not obtainable, and it is useless for the physician to advise change of air; but to the man of means it is a want that can be supplied, and the question arises as to the choice of place. There are many Spas, but few really good ones; and to decide upon any one in particular, where natural conditions are accompanied with the comforts of home life, becomes a difficult matter.

All these requirements can be obtained at the Bedford Springs. They are situated in the Allegheny mountains, 256 miles west from Philadelphia *via* Penna. R. R.; and 160 miles from Pittsburgh. Here for centuries nature has been pouring forth with her usual lavishness, one of her remedial agents for dyspeptic troubles. The action of this water upon the system might be termed a magnesia purgative, but the purgative action is very pleasant and gentle. Sulphate of magnesia is the principal ingredient, from which the purgative action results. And this effect is much improved by the lime and iron it contains, as it builds up the system at the same time it is helping to remove the waste material. The accompanying accurate and complete analysis of the water by Prof. Leffmann, of Philadelphia, will speak for itself:

BEDFORD MAGNESIA WATER.—*Results of Analysis of Water from Springs known as Magnesia Springs, Bedford, Pa.*

	Grains to O. S. G.
Calcium carbonate	7.55
Ferrous carbonate	0.06
Calcium sulphate	103.61
Magnesium sulphate	41.34
Potassium sulphate	0.09
Sodium sulphate	0.34
Sodium chloride	0.45
Silica	0.42
Calcium phosphate	0.01
Lithium	Traces
Strontium	Traces
Nitrates	None
Nitrites	None
Fixed organic matter	None
Total solids	153.87

The water of the magnesia spring is noticeable from its large proportion of active mineral ingredients, especially the magnesium sulphate (Epsom Salts) which confers upon it a mild aperient quality. The high degree of organic purity is also to be noted. The absence of organic matter, nitrates and nitrites, together with the very low figure for sodium chloride, indicate that this water arises from sources deep in the earth, and free from any of the polluting influences to which surface waters and superficial springs are liable. As drawn from the spring the water is perfectly clear, and retains its qualities unchanged for a long period, the active ingredients being held in solution by their own properties, and not by any accidental association.

This shows that the chief remedial agent present is the magnesia sulphate, slightly combined with the iron. How valuable these products are combined, in the treatment of the many diseases resulting from an abnormal condition of the digestive system, is well known to all of us, and particularly so to the hospital physician.

I remember when I was connected with the London hospitals, that the most favorite medicine called the "white medicine" was a combination of magnesia carbonate and sulphate. How quickly does the anæmic woman who comes complaining of irregular menstruation, fainting attacks, constant headache, costiveness and general depression, regain her strength when she takes the magnesia sulphate and iron combined. Here we have a natural combination and it is surprising to note the rapid strides toward health that the invalid makes after he has been taking the water for only a short time.

To the gouty dyspeptic the water is a most valuable aid toward complete restoration of health. I have always been forcibly impressed with the fact that the action of mineral waters generally is considerably enhanced when they are taken when the brain and nervous system are resting; and the greater the change of scene that is provided for the over-taxed nerve centres, the greater is that rest. The natural surroundings of the Spring cannot be equalled; mountain and valley are intermingled in that artless manner so characteristic of the designing hand. The eyes are enchanted with the majestic growth of forest trees, the luxuriance of the vegetation, the gorgeous colors of the flowers and insect life, and the ears are lulled with the rippling music of the mountain streams as they rush over their pebbly beds. Any taste for natural pursuits can be cultivated. The shooting and fishing are extremely good. Here the visitor finds he can wander for miles where he likes with rod or gun, and need not fear to be disturbed by the game keeper, as would be his fate in the neighborhood of the English or European Spa.

Added to this there is a hotel fitted up with the latest improvements and requirements of the nineteenth century. It is situated about one mile from the town of Bedford, and lies pleasantly situated amongst the trees in a pretty vale. The drives and walks are numerous, most of them meandering for miles through forest vegetation, teeming with objects of interest. With such surroundings the invalid or holiday seeker cannot help being restored to health; and when he returns to the busier tasks of every day life, he has a brain stored with the reminiscences which are always so pleasant to recall.

New York Correspondence.

Clinics by Drs. Polk, Bulkley, Loomis, and Peabody: Views of Prof. Polk on Alexander's Operation.

Prof. W. M. Polk, at the clinic at Bellevue Hospital showed a patient, a domestic, 23 years old, who was sent to the hospital Jan. 17, by a reputable physician, as a case of simple chronic gastritis. Her history revealed that in the third week of last October she menstruated for three days and then ceased until December 1, after which she flowed profusely, at intervals. On January 1, a small grape-like mass came away with much blood. Nausea and vomiting began early in December, and became so severe that the patient could eat nothing and became very weak. On her admission to the hospital her temperature was 100°, her pulse 112 and very weak, her mouth and tongue brown and dry, and her breath offensive. Physical examination showed a tumor in the pelvis extending up to the umbilicus, of the size and shape of a uterus in the fifth or sixth month, and slightly tender on pressure. The os was not soft, but was dilated enough to admit the end of the index finger. January 19 and 20 more of the grape-like gelatinous masses with a decided odor of decomposition, came away, and the tumor declined in size. Dr. Polk made the diagnosis of hydatiform degeneration of the chorion, differentiating it, chiefly by the length of the history, the appearance of the masses, and by exclusion, from endometritis, polypus, fibroma, and mole. The os being sufficiently dilated, he emptied the uterus with a double curette, washed it out thoroughly with hot water and packed it with weak iodoform gauze, which was renewed after twenty-four hours. The patient had no fever and is now on the high road to recovery.

This treatment of curetting, washing out with hot water, or 1 to 5000 solution of bichloride of mercury, and then packing with weak iodoform gauze is one constantly used by Prof. Polk in chronic endometritis of the hemorrhagic or fungosum type, in septicæmia from retention of membranes, and similar conditions. With him and in Bellevue Hospital it has yielded brilliant results.

The Reporter, January 26, contained an editorial on Alexander's operation of shortening the round ligaments, its indications value, etc. This is an operation introduced into the United States and advanced to its present high standing by Prof. Polk, and as his views differ somewhat from those advanced in the Reporter, they are herewith presented.

The effect of shortening the round ligaments is to draw the uterus upward and forward, so that the fundus can be placed directly behind the symphysis pubis. Consequently the operation is indicated in procidentia. This is the joint result of rupture of the perineal structure and stretching of the uterine ligamentous supports, chiefly utero-sacral, and the basic lines of the broad ligaments. The principal perineal support is the pubo-coccygeal division of the levator ani muscle. Prolapse is usually accompanied by backward displacement and hence Alexander's operation corrects both conditions, and then, when supplemented by restoration of the pelvic floor, it is both rational and satisfying. Among other indications are retroflexions and retroversions of the uterus, in which the organ can be placed in the normal position by the sound, and yet a pessary cannot be comfortably worn. So long as the uterus cannot be replaced easily, it is outside the domain of the operation, and the only alternative is abdominal section, tearing up the adhesions and removing the tubes if necessary. Another indication is prolapse of the ovary, provided it is reducible and not large enough nor diseased enough to require removal. The objections raised, that sometimes the ligaments cannot be found, and that they are not strong enough to hold the uterus, are unfounded. Dr. Polk, in more than half a hundred operations, has never had the slightest trouble in finding them, and experiment has proved that they are capable of supporting four to five pounds or more. So far as he has had opportunity to observe, the shortening does not interfere with pregnancy. One of his cases went to term and another is now pregnant and soon to be confined. As to danger, he thinks that, with thorough cleanliness and antisepsis and a knowledge of the anatomy of the parts, there is practically none. Up to Jan. 1, 1889, he had operated on fifty-five cases—more than any other man in America has performed. His results have been uniformly good, and only in one known case has the malposition recurred.

Dr. L. D. Bulkley, at his clinic on diseases of the skin, in New York Hospital, Jan. 28, had a typical case of lupus erythematosus, for which he recommended, internally, Thompson's tincture of phosphorus, ℥xv, t.i.d.; and locally:

℞ Potass. sulph.,
Zinci sulph. . . . . āā ℥j
Glycerini . . . . . f℥j
Aquæ rosæ . . . . . f℥iv

M. Sig. Apply freely.

Prof. A. L. Loomis, in a lecture on the treatment of acute lobar pneumonia last week, recommended the following: Counteract the shock of the first few days with opium (morphine hypodermically); keep the temperature down with quinine; when the heart begins to fail, *and not before*, use your stimulants, giving brandy at first. If this fails, sustain the heart and carry it past the crisis with citrate of caffein, in five grain doses every five or six hours. It acts on the nervous system rather than on the heart muscle itself, and is not diuretic. Digitalis he thought contraindicated in an uncomplicated case, and convallaria and strophanthus too unreliable for use. If pulmonary œdema comes on, relieve it with dry cups. Calomel, to unload the portal system, is dangerous because of its depressing effects. Counter-irritants are also bad, and he uses instead the flannel and oil-silk jacket or a hot mush or flax-seed poultice that completely encircles the thorax. This should be applied as hot as can be borne every two hours, and will give much better satisfaction than a poultice over only a portion of the lung. Expectorants are of no service unless the mucus is very tenacious, when small doses of the muriate of ammonia can be given. Large doses are contraindicated, as they upset the stomach, while as a heart stimulant the drug is inferior to champagne. The use of cold is likely to do harm. To this treatment he adds absolute rest, a diet of milk, eggs, broth, etc., and uses the ordinary remedies for cough and other symptoms that may arise.

Dr. G. L. Peabody, on Jan. 31, held the last clinic of his spring course in New York Hospital. It consisted mainly of an array of old cases. Among them were several convalescing cases of typhoid fever which had been treated with resorcin. The results seemed very satisfactory, though the Professor was unprepared to give an opinion of its comparative utility. A case of chronic gastritis which had been treated with daily washings of the stomach, with steady improvement, showed a relapse, having great pain, vomiting, temperature 102°, aching bones, etc. The patient—a young woman—is taking extract of malt and a fluid diet, and her secretions are being regulated with aloes and myrrh. It was decided to withhold the washings for a few days.

A case of peripheral neuritis of alcoholic origin showed marked benefit from a long course of strychnine. His insomnia was best treated with paraldehyde in doses of f℥j–ij, though urethan, in doses of gr. 100, did very well.

A painter with wrist-drop from lead-poisoning was regaining the power of extension under iodides. His face presented a well-marked iodide eruption, being covered with pustules. He was a man who had suffered with rheumatism and gout, and during his present illness a joint affection came on at the knee. To be sure to strike the disease, the doctor prescribed (successfully) medicines to meet both conditions, viz: iodide of sodium and wine of colchicum. This brings to mind a similar double-barrelled prescription, it being the rheumatic mixture of Bellevue Hospital. It is:

℞ Sodii salicylat. . . . . gr. x
Vini colchici . . . . . ♏ v
Pot. iodidi . . . . . gr. x
Aq. cinnamomi . . . . ad f℥j

M. Sig. One dose.

Perhaps the most interesting case presented was one which has baffled Prof. Peabody and the entire staff. It is that of a servant-girl, aged 17, single, and coming from Denmark. Last summer, the patient entered the hospital with a high temperature. There was no apparent cause for it, but up it stayed, reaching normal about twice every three weeks or so. Pain was developed in the right iliac fossa, the diagnosis perityphlitis made, and laparotomy performed. The appendix was found in a healthy condition, and no pathological state could be found in the neighborhood. The patient left last September and was gone three months, returning in November in the same condition. Since then, her temperature has ranged constantly from 102° to 105° and even higher. Quinine seems to act best in controlling it. Besides the temperature, until January 30, she had no other symptoms; none in the chest, abdomen, nor kidneys—though sometimes her pulse and respirations became very rapid. She eats well, suffers no pain, and loses little or no weight. January 30, she had a chill, and her fever went up to $108\frac{6}{10}°$. Next day, she had a similar experience, and then under phenacetin the temperature was kept down to 103°. What the affection is, the Doctor does not know. All that can be done is to combat the fever.

LETTER FROM BERLIN.

An Ideal Laxative Suppository—An Interesting Demonstration of Hypnotism—Vile Abuses of Hypnotism—Singular Results of Arsenical Poisoning—Thiol and Ichthyol—The Wachsmuth Treatment of Diphtheria—The Bee-sting in Rheumatism—Medical Candidates in Germany.

Berlin, Jan. 25, 1889.

The history of the at present fashionable employment of glycerine as a laxative is rather interesting. Dr. Oidtmann, a physician of Maastricht, Holland, who cared less for the Dutch code of ethics than for the almighty dollar, did for years a flourishing business by advertising his infallible and instantaneously acting purgative. As he did not appear to get rich fast enough the German government came to his assistance by forbidding its sale as a secret remedy, and publishing at the same time an analysis of it. The natural result of this proceeding was a tremendous demand for Dr. Oidtmann's purgative on the part of all who were troubled with constipation. The analysis having proved that its essential constituent was simply glycerine, the profession itself soon took hold of this drug in the treatment of constipation. The fact is that glycerine applied to the rectum, in slight cases of constipation, acts really as a prompt, though scarcely as an energetic laxative. The question why glycerine exerts a laxative influence has been answered variously, though it cannot be said that its *modus operandi* has as yet been definitely established. Some regard its action as a reflex phenomenon due to the local irritation of the drug; others believe that glycerine acts like an alcohol, causing (like ethylic alcohol, for example) a rapid abstraction of water from the part, which in turn causes increased peristaltic movements of the bowels. It has been suggested that a similar process—on a grand scale—takes place in cholera, where the rapid desiccation of the mucous membrane of the bowels leads to muscular cramps.

The application of glycerine by the mouth and by the rectum by means of a syringe was soon superseded by suppositories prepared from glycerine and oil of cacao, which again were replaced by hollow suppositories, filled with glycerine. But the greatest improvement was reached by the introduction of glycerine toilet-soap as the most perfect and most convenient laxative suppository. The soap, being very plastic, the patient can make suppositories from it at any time without any preparation whatever. The action of the glycerine-soap suppository is very prompt, a few minutes sufficing to produce a gentle movement of the bowels. It must be admitted that for ease and convenience of application, for economy and prompt action, this new form of glycerine suppository is an ideal laxative which, especially for women and children, cannot fail to become popular soon.

Hypnotism, in spite of its highly interesting features, many physicians are loth to approach, partly because they regard their established prejudice and skepticism as invincible, and partly because they do not care to enter a new domain of science, in which there is demonstration but no explanation. It seems that the German physicians, who thus far have left the exploration of this interesting field to their French colleagues, have of late taken more interest in the matter. Prof. Mendel, the eminent neurologist of the Berlin University, recently gave a highly interesting representation of hypnotism before a small and select group of medical men. The patient was a young man, 25 years old, who, on account of weakness in the lower extremities, could only limp in walking. Prof. Mendel told the patient to close the eyes; this he did and immediately fell asleep. He remained in a sound sleep even after having opened his eyes again at the word of the Professor. Then the patient at once showed no more traces of his former disability, but could walk as easily and uniformly as a sound man, could mount a chair and perform other movements regarded previously as absolutely impossible. To increase the surprise of the gathering the patient, who previously stammered to such an extent that he was unable to enunciate two consecutive words, began now with considerable oratoric skill to recite "*Des Sänger's Fluch*" (the minstrel's curse), by Uhland. When told that an organ was close at hand, he directed the hymn "Jesus, Lover of My Soul" to be sung, and he intoned it at once. Another interesting feature of the *séance* was the following performance: The patient was given five blank postal cards with the "suggestion" that on one of them the letter A—the beginning of the patient's name—was written. This card was then marked by a dot on the other side, and five cards, after having been thoroughly mixed, were handed to the patient, who without hesitation selected the

marked card. Prof. Mendel regretted his inability to give a satisfactory explanation of the remarkable facts witnessed. Regarding the card feat, he thought that the hypnotic state possibly sharpened the optic faculties of the medium.

This hypnotic performance recalls to your correspondent two cases of vile abuse of hypnotism, which some time ago came before the French law courts and created a profound sensation. A crippled beggar, 25 years old, went to a farm-house occupied by an intelligent and wealthy family, and asked for alms. He represented himself as being a deaf-mute and in need of something to eat. During the meal he made some strange gestures, for instance the sign of the cross over his face and over everything he ate or drank. Asking for a piece of paper he wrote down the following: "I am the Son of God; I come from heaven and my name is 'Our Lord'; you see my small miracles, later you will see grander ones; do not be afraid, for I am sent by God."

These words made a deep impression upon all present, especially on the daughter, a young lady of beauty and accomplishment. The beggar spent the night in a barn and next morning went to the house again, where he found the young lady alone. He conversed again with her by gestures and made the sign of the cross repeatedly with his fingers on her back and forehead. During the meal he stared at the lady so intently that she suddenly sank from the chair in utter exhaustion, whereupon he disgraced her. Though she knew what was going on she could offer no resistance nor utter a cry; she was restrained by some strange, powerful force and evidently in a state of lethargy. At his suggestion the lady left her home, went along with him, stopped with him at night in a neighboring barn, and was a powerless tool for the vilest of his designs. If at any time she was about to return to consciousness regarding her situation, a mere touching of her hips (hypnotogenic zone) sufficed to put her again into somnambulism and bondage. Witnesses testified that she executed automatically all movements suggested by him, laughed convulsively, glided on her knees about the room, mounted a ladder, caressed him with erotic fervor, etc.

Before the court he acknowledged having seduced the lady through hypnotism and suggestion, and that he had previously ruined several girls by the same method. He boasted before the jury that he could overpower the strongest and most unwilling girl and declared himself ready to prove it in court. He also volunteered to hypnotize the president of the court by the mere power of his eyes; but the latter avoided this predicament by turning his back to the defendant. The latter was sentenced to the penitentiary for twenty-one years.

The second case is that of a dentist, who hypnotized a lady patient in his operating chair, and disgraced her. This villain was also sentenced to the pentitentiary.

That an intoxication with such a poisonous drug as arsenic may have highly beneficial results must certainly be regarded as exceptional. A child two and a half years old, affected with obstinate enuresis and incontinence of the bowels, took by mistake some rat-poison and developed severe arsenical poisoning. Both conditions mentioned above were found to have disappeared after the child had recovered from the effects of the poison. But still more remarkable was the change noticed in the mental condition of the child. Before the accident it could say only the single word "mamma," and was exceedingly peevish; while after recovery it learned to talk rapidly, played alone for hours, and turned out to be a bright and good child. It is clear that the gratifying changes mentioned are to be ascribed to the alterative effects of the arsenic. Possibly two doses a day of Fowler's solution may be indicated not only for the disorders of the bladder and bowels, which existed in this case, but also for children with a retarded mental development.

"What's in a name?" In medicine, at least, we should think nothing; as long as the action of a drug is a desirable one, its name should neither favor nor check its popularity. Still it seems that even in legitimate therapeutics, especially among the lately discovered remedies, those with a soft-sounding and harmonious name have been victorious over those with less happy designations. There is, besides, an evident tendency to apply to newly discovered remedies names closely allied to successful predecessors. This is noticeable in the names of antipyrin and antifebrin; salicylic acid and salol; iodoform and iodol; ichthyol and thiol. Thiol, the latest claimant to professional favor, was discovered by Jacobsohn, who prepared it by distillation from brown coal-tar by the addition of flowers of sulphur. The mass is heated in an oil-bath up to 215° C. (419° F.); the sulphurated hydrates of carbon are first converted into sulpho-acids by the aid of sulphuric acid, and then by treatment with

ammonium or sodium hydrate into thiol salts. Thiol, or German ichthyol, closely resembles ichthyol, and is easily soluble in water or in a mixture of alcohol and ether. Its reducing power is shown by its conversion of ferric chloride into ferrous chloride and by instantly decolorizing permanganate of potash. Dr. Reeps, assistant of Prof. Schweninger, has subjected thiol to clinical trials and has pronounced it as the medicinal equivalent of ichthyol. The thiosulphate of sodium contains twelve per cent. of sulphur and is asserted to have anti-rheumatic virtues. A great advantage which thiol possesses over ichthyol is its cheapness. If Dr. Reep's statement should be confirmed, thiol has every chance of becoming a popular remedy. The value of ichthyol in rheumatism and skin affections is at present well established.

The vexed question of the most successful treatment of diphtheria is certain never to disappear from the professional forum. Recommendations and alleged miraculous successes have in this direction been so plentiful of late that the average practitioner has long ago ceased to be credulous. Still it is our duty at least to take notice of all novel suggestions of treatment. The so-called Wachsmuth treatment of diphtheria is at present, in Germany at least, attracting considerable attention. It is always applicable in children under five years of age, in adults, however, in graver cases only. The child is stripped, wrapped up in wet linen sheets, so as to leave only the head uncovered, and then covered with warm blankets or a feather-bed. The first application is best made by the physician himself, and the others can be made at intervals of several hours by a member of the family. Wachsmuth himself recommends to make an application lasting three hours and then to pause for two hours, and to prolong the period if improvement sets in. Gargles with a greatly diluted solution of corrosive sublimate, or better with a two to three per cent. solution of acetic acid, should be used also. Careful ventilation of the sick-chamber and a change of room for the nights, if possible, are likewise recommended. The results obtained with this treatment are said to be highly satisfactory; the fever being lowered in height and duration, the membranes being expelled rather easily, and the period of convalescence also shortened.

So-called household remedies and methods of treatment have been adopted by the regular profession not infrequently. A singular illustration of this is the employment of the bee-sting in gout and rheumatism, as originally advocated by Dr. Tere, of Marburg. This practitioner has used this old-fashioned and empirical treatment on 173 patients, on whom he produced altogether 39,000 stings. As the sting is manipulated by the practitioner, the latter, of course, has to avoid being stung himself. Light and acute cases are said to improve, or to be cured after a few stings, while in chronic cases hundreds of stings are required to produce a curative effect. In acute articular cases the bee-sting is said to have no advantage over antipyrin and salicylic acid, and is therefore here only applicable when the other remedies have failed. In chronic and complicated rheumatic processes especially, the bee-sting deserves to be tried. The application is also said to act with remarkable promptness in rheumatic pains of the heart when endocarditis and myositis are threatening. On account of its cheapness the bee-sting cure might be tried in the treatment of the poor.

It may be of interest to the readers of the REPORTER to learn of the number of medical candidates from States within the German Empire who failed last year in their final examination. The percentage of those who failed is 28; in Berlin and Breslau this percentage rose to 42 per cent., in Halle to 34 per cent. These figures are a fair criterion of the almost fatal severity of German medical examinations. It would really be a highly desirable improvement if the requisites of graduation in American medical schools were raised. There is no use denying the deplorable fact that with only a few exceptions the requisites of graduation in America are far below the European standard. Before attempting, however, any improvement in the direction indicated it is necessary that the course of medical training should have the compulsory length of four years, and above all that the preliminary examinations should be rendered more rigid. Unfortunately a uniform governmental supervision and regulation of medical education, which is found all over Europe, cannot well be introduced into America.

—The State Board of Health of New York notified the health boards in all parts of that State on Jan. 30, that small-pox has become threatening in the Onondaga county poorhouse, the penitentiary at Syracuse, and at Lyons and other places in Central New York. The Board urges all persons to be vaccinated, and a special lockout for tramps.

PERISCOPE.

Albuminuria of Pregnancy and Puerperal Eclampsia.

Dr. Lantos, of Buda Pesth, has recently made a series of observations on albuminuria of pregnancy in the wards of Professor von Kézmársky. His paper will be found in the *Archiv für Gynäkologie*, vol. xxxii, part 3. In over 18 per cent. of 70 pregnant women he found albumin in the urine, whilst in nearly 60 per cent. of 600 newly delivered women the urine was albuminous. Albuminuria was detected in over 70 per cent. of 268 primiparæ, and over 50 per cent. of 332 multiparæ. The percentage was distinctly lower in premature labor, and 50 per cent. lower in abortion cases. Out of 10 cases in which albumin was abundant so that Dr. Lantos used the microscope, he found pus in 3 and casts in 5, but no foreign elements in the remainder. He examined the kidney in 39 cases in which the patients had neither died from eclampsia nor from nephritis. In 15 of these cases the kidneys were very anæmic, in 21 pale, and only in 3 full of blood. Amongst the local changes in other cases he found acute parenchymatous nephritis in 2 cases, acute hæmorrhagic nephritis in one case, parenchymatous degeneration in 9 cases, and in 4 albuminous degeneration.

Dr. Lantos therefore concludes that, putting aside all evident and probable cases of nephritis in pregnant women, albuminuria is not rare in pregnancy, and very common after parturition. He refers the phenomenon to reflex irritation of the vasomotor nerves of the renal vessels; it has, he says, no pathological significance, and, in conjunction with other symptoms, is a valuable diagnostic sign of pregnancy. Out of 14,815 labors observed in the course of fifteen years, he noted 53 cases (0.36 per cent.) of puerperal eclampsia, a ratio of 278 to 1. Over 78 per cent. out of 42 eclamptic cases occurred in primiparæ, over 21 per cent. in multiparæ; 15 out of the entire 53 died.

Dr. Lantos thinks that the rate of mortality is increased when instruments are used, and as the convulsions often do not cease after delivery, he thinks that the forceps should not be used unless there are strong indications. Convalescence is much prolonged after eclampsia. In 23 of the eclampsia cases the urine was examined; in 21 it was albuminous, casts being found in 4. At the necropsies of fatal cases of convulsion, Dr. Lantos found constant changes in the brain, but only once acute, though frequently chronic, renal changes. Like Osthoff, he traces puerperal eclampsia to violent reflex vasomotor disturbance, and classes it as acute peripheral epilepsy.—*British Med. Journal*, Jan. 12, 1889.

Button-hook in the Intestines.

Mr. A. B. Kelly communicates the following account of this interesting case to the *Lancet*, Jan. 5, 1889.

On Oct. 31, 1888, I was summoned to see Mrs. D——, who, I was informed, had swallowed a steel bow-handled button-hook, three inches and a half in length. On arriving at the patient's house about a quarter of an hour after the occurrence, I found her seated in a chair, apparently more frightened than hurt. She stated that she had been picking her back teeth with the point of the hook, and the article slipped out of her hand during an act of inspiration and went down her throat. Evidently it had not lodged in the œsophagus, but had descended to the stomach. I requested the patient to assume the recumbent posture; and directed an attendant to administer some bread-and-milk as quickly as possible, and an ounce of castor oil about an hour afterward. On visiting the patient later on, I learned that there had been a copious motion, but nothing particular to note. I saw the patient daily afterward for about a week, she remaining in bed for a few days. There was a daily evacuation, but no sign of the hook. I recommended food consisting of pudding of doughy material, and a moderate allowance of meat, hoping to form a coating round the hook. Further, I gave directions for castor oil every other day, and a mixture of linseed decoction to be administered three or four times daily. I asked the patient to send for me should any urgent symptoms arise; but I heard no more of the case until Nov. 23, or just three weeks after the hook was swallowed. The defecations had been passed daily into a night-stool and watched, when, to the patient's great relief, on the day just mentioned, she found the hook had passed from her bowels, but without any coating of food. There was, however, a brownish-black discoloration over its entire surface.

Pins, coins, etc., have repeatedly been swallowed, but I have seen no case recorded in which such an article as a button-hook has been swallowed.

A Good Bread for Diabetics.

In a communication published in the *Boston Med. and Surg. Journal*, Jan. 24, 1889, John A. Jeffries spoke of a good bread for diabetics. All are now doubtless aware, he said, that the so-called gluten flours are not what they should be, and will agree that the first thing in the treatment of diabetic patients is the avoidance of starches and sugars. It is therefore very desirable to get a bread, or more accurately a substitute for bread, which will satisfy the cravings of the patient for bread and yet fill the therapeutic indications. Experience seems to show that the craving is not for starch but for the form and taste of the bread; that is, for the sensations produced by such food in the mouth and nose by the senses of touch, taste, and smell, not for starch in the stomach and intestines. Were this not the case, he said, it would be impossible to satisfy the patient's wants.

He showed samples of bread which he thought much more nearly fulfilled the requisites of the case than any now in use. He has succeeded in preparing two kinds, one simply an improvement on those now in use but easily procured and inexpensive; the other a great improvement, but at present difficult to procure and expensive.

The first is made by using equal parts of bran and graham flour, or, put in accurate form: One cup of graham flour; one cup of best bran previously scalded with one cup of boiling water; two eggs; German yeast or baking powder; salt to taste; one cup of milk or water. To be mixed with a *spoon*. Such a bread contains 17.72 per cent. of starch, the equivalent of 19.68 per cent. sugar.

The second is made from the gluten of the starch factories ground to a fine flour. In the ordinary method of manufacture, he said, the gluten is fermented out and lost, but lately efforts have been made to separate it out by machinery for sizing. The bread is made as follows: One cup gluten flour; one cup best bran previously scalded; one teaspoonful of baking powder; salt to taste; two eggs; one cup of milk or water.

To be mixed with a *spoon*. If the hands are used the result will be even more disastrous than in the making of ordinary bread. This bread is wholesome, palatable, nutritious, and contains but 4.57 per cent. of starch, equal to 5.08 per cent. of sugar. The analyses were made by Dr. Charles Harrington.

Dr. Jeffries thinks this bread is practically the same as that described by Waltering in the *Allgem. med. Central-Zeitung*, August 4, 1888.

In answer to the question by Dr. A. N. Blodgett, why Dr. Jeffries thought it is so essential that this bread should be made with a spoon, Dr. Jeffries said that all bread, even ordinary bread such as everybody has, is much better when not touched with the hand, and this is especially true of this gluten bread. Some of the gluten he exhibited is separated out for manufacture and used as shoemakers' wax in Germany. If it is worked with the hand it is apt to be soggy and not rise at all; if worked with the spoon it will rise nicely.

Lactic Acid in Chronic Suppurative Otitis Media.

Isidor Herrmann, according to the *Therapeutische Monatshefte*, Dec., 1888, has obtained the best results in chronic suppurative otitis media from the use of lactic acid, and this in cases which defied other treatment. He instils daily into the middle ear a few drops of the diluted acid, which is allowed to remain there about twenty minutes. Usually the bad odor, due to the purulent excretion, disappeared after three or four applications of the acid. The discharge itself ceased after about six weeks' treatment. Moderate ulcerations in the drum healed, after topical treatment with the mitigated stick of nitrate of silver, within a few weeks after the discharge had entirely ceased.

Before the acid is applied, both the external meatus and the outer surface of the drum-membrane should be protected with vaselin, oil, or some such agent, in order to avoid direct contact of the acid with parts which are so prone to inflammation. A twenty per cent. solution of lactic acid is first used, and gradually increased in strength up to forty per cent., if the patient bears the weaker solution well. After the application of the acid finely pulverized boric acid is blown into the ear, under the employment of which small perforations in the drum-membrane heal. If moderate ulcerations in the drum-membrane show no tendency to heal, then the employment of an artificial drum-membrane is indicated, which the patients for the most part bear. If they do not, then a relatively large quantity of boric acid is blown into the middle ear, to give adequate protection to it. Usually the boric acid melts with the secretion of the ear and forms a moderately resisting circular wall with only a small opening in the centre; in this way an artificial drum-mem-

brane is formed and the hearing decidedly improved.—*Wiener med. Presse*, Dec. 30, 1888.

Treatment of Typhoid Fever.

Ziemssen (*Centralblatt für klin. Med.*, No. 6, 1888) attributes the lowered mortality of typhoid fever within the past few years to improved therapeutics. Only a few of the more important features of his very extensive and scientific paper can be given. The patient's room should be capacious, quiet, and well ventilated. Water-pillows should be used, and, when possible, a second bed. The author is in favor of easily digested albuminates during the fever. Beef-juice extracted from fresh beef is the most suitable, and of this the patient should have 150 to 200 grammes (5 to 6½ oz.) in twenty-four hours. Regarding other forms of nutriment, the author follows the prevailing methods. Gelatin is often given in form of calves'-foot jelly with wine. The author gives but few medicines, and these only when specially indicated. Calomel, he thinks, has a decidedly beneficial effect when given at the right time—that is, within the first five days of the illness. He gives seven and a half grains three times within two hours. Strong emphasis is laid upon his method, which is so well known, of reducing the temperature by graduated cold baths. He speaks warmly of antipyrin as an antipyretic, of which he administers 5 grammes (grs. lxxv), in three divided, hourly doses, beginning the administration after 6 P.M. Thallin and acetanilid receive praise from him, but he condemns quinine, because it is attended with untoward effects—such as noises in the ears and an indescribable sensation all over the body. Kairin and salicylate of sodium as antipyretics he considers antiquated. In slight cerebral symptoms an ice-bag should be applied to the head, but not continuously; in severe cerebral symptoms, graduated baths, with cold affusions, are indispensable. Insomnia and restlessness are best combated by an injection of morphine. A tendency to cardiac weakness is best met by excitants, the best of which are camphor and wine, champagne and brandy. Severe diarrhœa is best treated with starch and opium enemata. Intestinal hemorrhages call for ice-bags on the abdomen, and subsequently for ice-water enemata, which act reflexly. The intestinal hemorrhages which occur between the fourth and sixth weeks offer a much worse prognosis than those that occur during the second and third weeks. Bed-sores can be avoided by care, cleanliness, cold-water treatment, and a water-pillow.

During convalescence great care must be exercised regarding the diet. For five days, at least, after the non-febrile period has set in, the diet should continue to be of a liquid nature. After this it may be given in a semi-solid form for a few days, and then solid food may be cautiously given. The patient should keep in his bed for fourteen days, even after a mild attack, and for three or four weeks after a severe one.—*N. Y. Med. Journal*, Jan. 19, 1889.

Tumor of the Brain and Accidental Injury.

The following case, observed by Dr. Kaufmann (*Vierteljahresschrift für gerichtliche Medicin*), is interesting chiefly from a medico-legal point of view. A house-painter was thrown from a ladder, striking in his fall the corner of a piece of furniture. From this time on, violent headaches and pains in the back were frequent. Immediately after the fall he remained for several hours unconscious. After slight and transitory improvement, during which he returned to his work, the head pains returned, mental weakness, slowing of pulse, narrowing of the field of vision, and loss of appetite came on. Transitory mania was also observed during the cephalalgic attacks; finally almost total blindness and paralysis of the left arm supervened. Death took place six months after the accident. Post-mortem examination showed death to have resulted from a sarcoma. The tumor was of comparatively recent growth; the oldest pathological cerebral lesion was evidently an apoplectic cyst which was surrounded by a cheesy tumor. This cyst was pronounced by the pathologist to correspond to an effusion of blood of such amount that it could not have taken place without visible symptoms. It was extremely probable that the hemorrhage was the result of the fall, and that the loss of consciousness noted was dependent on it. The hemorrhage was the direct cause of the development of the tumor, as injuries, falls, and the like were undoubted and recognized causes of cerebral tumors and their most frequent explanation, especially in the case of sarcomata. All other explanations were only hypotheses. The histological examination of the tumor explained its rapid development in so short a time. The conclusion was that the fall led directly to the development of the tumor, and through this to death.—*Med. Record*, Jan. 26, 1889.

The Place of Saccharin in Pharmacy.

Under this title, Professor Attfield, F.R.S., one of the editors of the *British Pharmacopœia*, gives some very practical information as to the formula and uses of saccharin, in a pamphlet just issued from the press. By way of introduction, he observes that saccharin will be of good service in pharmacy in four ways. First, it will give patients an opportunity of taking certain medicines in comparatively small bulk. Many medicinal confections, powders, and lozenges have hitherto necessarily contained large proportions of sugar. A mere trace of saccharin put in place of sugar, while rendering the medicament as sweet as before, will give such a reduction in bulk that, for example, a bismuth lozenge will become a mere pellet, and compound liquorice powder, or confection of senna, be reduced to half their old volume. Second, the intensity of the sweetness of saccharin will enable it to mask the nauseous taste of certain medicines, the flavor of cod-liver oil, for example, being well disguised. Third, patients who are obliged to avoid sugar will no longer be deprived of its property of sweetness, for not only tea, coffee, cocoa, etc., but many medicines also, containing saccharin in place of sugar, will once more become palatable—sweet, but not harmfully sweet. Fourth, saccharin not being liable to ferment, while sugar is specially prone to ferment, its use will afford permanent preparations where those made with sugar will frequently spoil. The exhibition of saccharin will present no difficulties. In prescriptions for fluids, such as gargles, mixtures, and emulsions, where physicians would have ordered a given quantity of solution of sugar (syrupus) they will prescribe an equal volume of simple solution of saccharin (sol. sacc. simp.). In prescriptions for a powder, or a confection-like mass, saccharin itself might be prescribed. And most of the large number of galenical preparations, as commonly ordered by physicians, and now made with sugar, would be prepared with saccharin, and would be set forth in prescriptions under distinctive names—mist. cretæ sacc.; pulv. glycyr. co. sacc. concent.; conf. sennæ sacc. concent., etc. Concerning incompatibles, saccharin is a tolerably indifferent substance. It is unaffected by the fluids of the body, acid or other, for it has been proved to pass through the system unchanged. Fusion with caustic alkali gives a salicylate, hence prolonged contact with strong alkalies is probably undesirable; and, obviously, acids would precipitate saccharin itself from a strong, though not from a weak, solution of a soluble saccharinate, that is, "soluble saccharin"; but saccharin is quite anaffected by the ordinary materials used in medicine. Professor Attfield regrets the name saccharin, and suggests "neo-saccharin," or an equivalent. He furnishes a considerable number of interesting formulæ.—*British Med. Journal*, Jan. 26, 1889.

Communication of Tuberculosis.

An instructive case of communicated tuberculosis is related by Dr. E. von Duhring, who states in the *Monatshefte für prakt. Dermatologie*, No. 22, 1888, that a girl 14 years old sprung from a family uncontaminated with phthisis, was in friendly relations with a young girl who died of consumption. At the time when this girl died the patient, E. Z., was in good health. Shortly after the death of the friend she removed the earrings which the other wore from the ears and fastened them in her own. The mother stated that the girl who had died had no wound in her ear, but E. Z. herself, on the contrary, states that her friend had frequently blood and matter on her ear. The patient E. Z. herself had up to that time never worn earrings, although the ears had been bored for the purpose. Shortly after she began to wear earrings the hole through which they were fastened began to secrete freely, notwithstanding which she continued to wear them, and she had continued to wear them up to the time when Dr. von Duhring saw her. It was on account of the condition of her ears that she was brought to him. He found her pale, somewhat thin, but well built and well developed for her age. Where the left ear had been pierced there was a shallow ulcer with undermined borders, and on the left side of the neck there was a slightly enlarged gland adherent to the skin, which was ulcerated on the surface and covered with a dirty scab. On removing the scab a somewhat abundant thin secretion escaped. The borders of this ulcer were irregularly dentated. On examining the lungs, there was dulness detected in the left apex. Granulations removed with a sharp spoon from the wound in the ear showed the presence of tubercle bacilli. The further progress of the case was rapid, and at the time Dr. von Duhring wrote his paper the patient was rapidly sinking from phthisis.—*British Med. Journal*, Jan. 19, 1889.

Action of Ergot on the Uterus.

Dr. Lombe Atthill, in a communication published in the *Dublin Journal of Medical Science*, Dec. 1, 1888, says of ergot that it is most uncertain in its action and in its effects. In some cases it causes pain, and when it does it always, he thinks, lessens hemorrhage from the uterus, the pain being evidently due to clonic contraction of the muscular fibres. But sometimes the same dose of the same preparation which caused pain previously, does not do so on another occasion, though apparently no change has taken place in the patient's condition. Dr. Atthill thinks that ergot will not induce clonic contraction of the uterine fibres unless something acting as a foreign body is present in it. The mere presence of a foreign body is not sufficient; it must be acting. Pedunculated polypi, he says, are commonly enough met with in the uterus, but their expulsion by painful uterine action is quite rare, and it is most likely that the seat of the tumor is the main element of its tendency to excite uterine action. The portion of the uterus between the entrance of the Fallopian tubes is the sensitive portion of the organ, and, in his opinion, it is necessary for a tumor to be situated there for it to act as a foreign body.

He regards it as very doubtful if ergot ever originates clonic contractions of the uterus during pregnancy, unless the organ is prepared by some pre-existing cause to expel its contents. When engaged formerly in midwifery practice he was in the habit of frequently prescribing ergot as a preventive to *post-partum* hemorrhage, commencing its administration a week or ten days before the expected advent of labor, and he says he has never once had reason to suppose that it hastened that event; on the contrary, in several instances the period of utero-gestation seemed to be lengthened. In like manner, in cases of a threatened abortion, he has seen the hemorrhage checked, and pregnancy proceed normally under the administration of ergot; it seemed, indeed, to act as a uterine tonic, if such an expression be admissible. In others, and perhaps the majority, it seemed to produce no effect at all; in a few it induced clonic spasms, but in these there was always reason to think that the ovum was already blighted. In cases of uterine fibroids, he says, ergot will, in general, be found to act most beneficially in lessening hemorrhage when the tumor is embedded in the muscular tissue, and as thinning of the wall takes place, and as the tumor consequently comes in closer contact with the uterine mucous membrane, the result of its administration will be less satisfactory; but in all cases much will depend on the preparation used and upon its freshness.

Rickets, Rheumatism, Chorea, Cancer, and Urinary Calculus in the British Islands.

The *British Med. Journal*, Jan. 19, contains the report of the Collective Investigation Committee of the British Medical Association regarding the geographical distribution of rickets, acute and subacute rheumatism, chorea, cancer, and urinary calculus in the British Islands. The following is a summary of the report:

1. That there is no district in the British Isles in which acute and subacute rheumatism and malignant disease are not common in the sense defined in the inquiry paper. Of varying degrees of prevalence above that point this inquiry was not designed to furnish a criterion.

2. That rickets, though not unknown in rural districts, is mainly a disease of towns and industrial regions, and especially of large industrial towns; that it is rare in the rural districts of Scotland, the North of England, North Wales, and Ireland, Ulster excepted; that it is more common in the rural districts of Ulster and of the rest of England, and exceptionally prevalent in Cornwall, Kent, and North Essex.

3. That chorea, like rickets, is mainly a disease of towns and industrial regions, though by no means unknown in rural districts; that it is fairly evenly distributed in the rural districts of the four countries; that it is rare in seaside watering-places; and that it is, by exception, somewhat rare in the south as well as the west of London, and not, generally speaking, common in Glasgow, even in the poorer quarters.

4. That the distribution of chorea is further affected by that of acute and subacute rheumatism, its prevalence diminishing as the latter disease becomes rare.

5. That urinary calculus exhibits a decided tendency to affect the eastern sides of the two islands; that its chief seat in South Britain is the county of Norfolk, from which it radiates into the neighboring counties, and in North Britain the angle of land above Aberdeen, from which it extends down the east coast to the Forth; that it shows a less decided tendency to appear in the coalfields, being especially prevalent in the Black Country; and that its prevalence does not otherwise seem due to geological conditions.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.00**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

DECEPTION OF A MEDICAL WITNESS.

The daily papers report from Chicago that at the trial of a woman for murder, Dr. Kiernan, while testifying as a medical expert, was made the victim of a shameful trick by one of the attorneys for the defense. The latter held in his hand a volume of Ray's Jurisprudence and read an account of a case, pretending it was printed in the book. It was, however, written on pieces of paper which he had concealed between the leaves, and when Dr. Kiernan—as the story goes—said he was familiar with the case, the lawyer took the paper out and said he had concocted the account himself.

According to the published reports, this *dénouement* filled Dr. Kiernan with mortification, and the prisoner and her counsel with delight. This might well be; but there is another way of looking at the matter. As to Dr. Kiernan's part in it: it is not strange that he was caught in the trap set for him; because—as he stated—the account read was similar to many published in the books, and he might think he recognized it, and believe it was in almost any book on jurisprudence. In a similar case hereafter, he will no doubt ask to see anything read to him by an attorney at a trial; and this would be a good rule for all witnesses.

The lawyer's part in the occurrence merits the severest condemnation. Such dishonorable tricks are not indulged in by men of high character; and we know, from personal inquiry, that they are indignantly repudiated by the best members of the legal profession. To physicians the matter is one of more than general interest; because they are unfortunately often called to the witness-stand, and usually have an uncomfortable enough time there when attorneys keep within civil and considerate bounds. But the case will be far worse if physicians have added to the ordinary perplexities of examination and cross-examination the fear that they may be exposed to attempts to entrap them by what is virtually lying.

It is to be hoped that the occurrence which has prompted these comments will lead to some expression of opinion in regard to it on the part of representatives of the legal profession; for while a physician has been mortified and hurt by it, a lawyer has been disgraced.

There is no good reason why lawyers and doctors should not be the best friends in the world—many of them are; and we trust that the principles of professional comity will prevent a repetition of such an unfortunate occurrence as is described above.

ARTIFICIAL STIMULATION OF THE GROWTH OF BONE.

One of the well recognized curiosities of medical experience is the observation that the bones may sometimes rapidly increase in size under the stimulus afforded by disease or accident—or perhaps rather of the recoil from depressing influences. Similarly the bones of pregnant women increase in size under the influence of the heightened physiological activity of the state.

The occurrence of what may be called—somewhat inaptly—the pathological increase in size of bones was the subject of a careful study by Bergmann some years ago, who published the results of his investigations in the *St. Petersburger Zeitschrift*, Bd. xlv., and Ollier and Langenbeck have made valuable contributions to the literature of the subject.

In a very recent article in the *Berliner klinische Wochenschrift*, Prof. Max Schüller, of Berlin, presents an interesting, though brief, review of the hitherto recorded observations in connection with the, so-to-speak, spasmodic growth of bone, and an able study of the application of the teachings of these observations to attempts at producing such growth by artificial means.

From his own investigations and experiments, as well as those of others, it seems clear that this form of growth can be looked for only during the usual period of development of the skeleton, and that it depends upon some stimulus acting upon the cartilage between the diaphysis and epiphysis of long bones. A few cases are on record in which the bones have suddenly increased in length after the apparent end of the growing period, and these seem to make it probable that an interstitial growth may take place after the connecting cartilage has ossified. But such observations are very rare; and it is difficult to understand how a bone can increase in length, except at its extremities.

Among the conditions which have given rise to lengthening of the bones are aneurism, and angiectasis, and universal development of the blood-vessels; but ulcers, fractures, inflammations of the joints, and even infantile paralysis have been followed by a similar result.

Ollier experimented on animals, with various irritations of the periosteum and medulla of the long bones, and found they provoked an increase in length of the bones. Schüller has had a similar experience, and finds that the growth is caused by communication of the stimulus to the connecting cartilage.

A number of surgeons have attempted to make practical use of the suggestions afforded by observation and experiment, and Schüller has followed up the idea of producing an artificial congestion in the bones with the object of increasing their length. This congestion he produces by means of a constricting rubber tube applied some distance above the point to be influenced so as to compress the veins, but not the arteries, of the parts. The application is made at first for only an hour or two, then for gradually lengthened periods, until it is continuous during the day and night. The application must be graduated so as to produce no pain, and so as to accustom the patient to it.

Schüller does not depend on this measure alone to provoke growth in the bones, but adds massage, exercise and careful nourishment of the patient, including the administration of food containing salts of lime. He has practised his method in two cases, with quite satisfactory results, and recommends it for further testing.

This interesting subject is worthy of careful study in this country, and it would be useful to have it taken up by those who have cases suited to experimentation with Schüller's method. In the many hospitals and homes for the crippled in America there must be many patients who might with advantage furnish an opportunity for confirming or correcting Schüller's opinions; and we commend them to the attention of

the surgeons in charge of these institutions, in the hope that they may prove to be correct, and be applied for the benefit of those who are deformed or injured.

HYSTERORRHAPHY.

Among the most trying and intractable cases which the gynecologist is called upon to treat are those of retroflexion of the uterus with fixation in the malposition. These cases are trying not only because it is difficult to treat them successfully, but also because it is often difficult or impossible to make out the extent of the diseased conditions present, and hence to decide upon the line of treatment indicated. Inflammation and prolapse of the ovaries, and disease of the tubes of varying degree, quite frequently complicate the retroflexion. Under these circumstances the practitioner, in order to effect a cure, has need of all his energies, and his best efforts will sometimes be without avail. It is especially in this class of cases that the comparatively new operation of abdominal section, separation of adhesions, and fixation of the body of the uterus to the abdominal wall above the pubes promises to do much good. Treatment by pessaries can seldom be employed in these cases; vaginal packing often fails to effect even a symptomatic cure; the operations of Alexander and Schücking are contra-indicated by the adhesions present; often the uterine appendages are healthy or but slightly diseased, and exsection of these structures is not indicated. Nothing remains to be done except the application of Brandt's system of massage, or hysterorrhaphy.

The name hysterorrhaphy, was given to the operation by Dr. Howard Kelly, of Philadelphia, one of the earliest, and an original worker in this field. It is evident that the nature of the operation is different, when on the one hand the abdomen is opened for the sole purpose of suturing the fundus to the abdominal wall—separating adhesions when necessary; and when on the other hand the abdomen is opened in the performance of some operation, such as removal of the uterine appendages, or ovariotomy, and the ventro-fixation of the uterus is simply supplemental to the procedure first undertaken. As more distinctly setting forth the nature of the operation done, Dr. C. C. Lee, of New York, speaks of primary and secondary—supplemental—hysterorrhaphy. While this classification is evidently of practical importance, it is plain that it can not be applied to all cases. The operator may purpose to do a primary, formal hysterorrhaphy, but after opening the abdomen, he may find greater disease of the uterine appendages than he had suspected, or some other condition requiring operative treatment, and thus the suturing of the uterus may become supplemental or secondary. As thus defined, secondary hysterorrhaphy has been performed for some years, Kœberlé having operated as long ago as 1869, and Tait and Thomas within the present decade. There seems to be no question as to the propriety of fixing the fundus uteri to the abdominal wall, whenever in the course of an intra-abdominal operation it is found retro-flexed and fixed, or markedly prolapsed.

Primary hysterorrhaphy was first done by Olshausen. According to Lee, it is indicated in cases of malposition of the womb with fixation from adhesions, which resist milder methods of treatment. Kelly and Sänger extend the indication to cases of intractable prolapsus, and retroflexion without fixation, thus bringing this operation in competition with that of Alexander.

While to many it may appear that already enough operations have been invented to be practised upon women, and that in the future progress should be made in prophylaxis, and in perfecting the technique of methods of treatment already in use, still we believe that there is a field of usefulness for this new operation in the cure of stubborn cases of retroflexion of the uterus with adhesions, and in exceptional cases of prolapsus.

IODOFORM AND CADAVERIN.

It is interesting to note that an explanation of the antiseptic properties of iodoform is offered by Behring, in the *Deutsche med. Wochenschrift*, Aug. 9, 1888, which calls in a chemical reaction between iodoform and cadaverin. Behring says that unadulterated cadaverin causes pus formation, but that when mixed with iodoform it has no such effect. In regard to its constitutional effect, Brieger has asserted that cadaverin was not a toxic alkaloid; but Behring says that it is, and that it gives rise in mice to a definite and regular set of symptoms. None of these symptoms, however, arise when mice are treated with cadaverin mixed with iodoform.

These assertions are laid before our readers as medical news. It will be seen that, in order to complete the Behring's theory in regard to the antiseptic properties of iodoform, it is very convenient to dissent from Brieger in regard to the action of cadaverin on the general system. Whether Brieger or Behring is right in this connection we cannot say; but iodoform will probably be used as an antiseptic for some time to come, no matter how its action may be explained by laboratory investigators.

ARTHRECTOMY AT THE ANKLE-JOINT.

The usual line of approach to the ankle-joint, for the purpose of removing from it tuberculous or fungous deposits, is behind the external malleolus. In this line the access to the joint is relatively easy, and the incision here does not implicate any important structures. But Dr. Meinhard Schmidt, of Cuxhaven, proposes a new method as specially adapted to the removal of the products of tuberculosis in the talo-crural, or ankle-joint. His method, as described in the *Centralblatt für Chirurgie*, Jan. 12, 1889, consists in making a vertical incision alongside of and parallel to the outer border of the tendo Achillis, the middle of which crosses the line of the joint, going through the deep fascia, and opening the capsule of the joint. After clearing out the posterior part of the joint through this incision, the anterior part is approached through a vertical incision carried over the front of the joint in a line passing between the tibia and fibula.

In this way Schmidt found that he could explore and operate upon the ankle-joint better than in any other; and he calls attention to the fact that the arrangement of the ligaments of the ankle-joint is such that effusions or growths within it protrude from it in front and behind, and so, as it were, approach the surgeon.

This is not the first time that it has been suggested to employ an anterior incision in approaching the ankle-joint; but it is, so far as we know, the first recommendation to combine an anterior and a posterior vertical incision for this purpose. The proposition seems entirely rational, and has been carried into execution by Dr. Schmidt with ease; so that it deserves the consideration of other surgeons.

THE PHILADELPHIA POLYCLINIC.

A few years ago the meaning of the word "Polyclinic" was almost unknown in this country, except to those few fortunates who had enjoyed the advantages of study in one of the teaching establishments called by this name in Germany or Austria. Now, however, the term is well understood, and polyclinics have been established in several cities in the United States. One of the first of this class was the Philadelphia Polyclinic, which was organized in 1883 by Drs. Levis, Morton, and others, and which has continued its work ever since. At present—as our columns have from time to time indicated—it is enlarging its facilities for clinical instruction of graduates in medicine, and making an appeal to the Legislature for a grant of money to aid it in erecting a building better suited to its needs, and to those of its students, than the one now in use.

We sincerely hope that this grant will be

made; and we call the attention of our readers in this State to the Philadelphia Polyclinic, because we believe it deserves their hearty support. It is, in the first place, the only institution of the kind in Pennsylvania, and for this reason has a peculiar claim for sympathy and support—if it deserves them. In the second place, it is an excellent institution, managed by competent and honorable physicians and surgeons, and calculated to be of great service to medical men, who have recently graduated and need closer clinical opportunities than teaching in medical schools or general hospitals affords, as well as to active practitioners, who can spare a few weeks at a time to revive their knowledge or to improve themselves in special branches or phases of medical science or art.

In this connection, we note that there seems to be a disposition, on the part of the two most important medical schools in this city, to encourage the development of the Polyclinic, which is in agreeable contrast to the attitude at one time assumed toward it. This is as it should be. The medical schools cannot successfully combine the teaching of under-graduates and post-graduates, and they do well to encourage those who can relieve them of part of the work. We therefore regard with pleasure the evidences of sympathy with the Polyclinic shown by the University of Pennsylvania and the Jefferson Medical College; for we believe that its success will not only prove an advantage to the whole profession in Pennsylvania, but also add to the reputation of Philadelphia as a medical centre.

British and American Continental Medical Society.—Our correspondent in Paris writes that it is proposed to form a Society under the above, or some similar, title, with a view to promote social intercourse and maintain good fellowship between British and American physicians who practise on the Continent. The membership is to be limited to British and American subjects who are actually engaged in the practice of medicine abroad.

It is suggested that the Paris exhibition will attract many medical men to that city during 1889. The French medical Societies will hold meetings, and much of interest to doctors will be seen, so that it would be a favorable time to hold a first meeting there, which might take the form of a dinner (after a preliminary sitting) when it could be decided what form the present idea should take.

A letter has been issued to a number of American and British medical men practising in Europe; and on receipt of answers, a local committee of ten or twelve English and American physicians will combine to make the temporary arrangements so as to suit the wishes of the largest number as to time of meeting.

The Presbyterian Hospital.—At the annual meeting of the Trustees of the Presbyterian Hospital, Jan. 22, a very encouraging report was read of the work accomplished during the past year. It is a pleasure to note that this admirable institution, which stands so high in the estimation of patients and of the community, is to be still better equipped for the coming year. The want of a suitable administration building has been a great hindrance to the work of the hospital, but such a building is now to be supplied through the liberality of one of the members of the Board of Trustees, who has authorized the announcement that he will submit to the Board for consideration plans for the building, and assume the entire cost of its erection, should it be the pleasure of the Board to accept his offer. The Ladies' Aid Society of the Hospital is also pledged to raise thirty thousand dollars for a new surgical ward. With certain changes and additions the hospital will then be able to accommodate about two hundred patients, provided the increase in its endowment and in the annual contributions from churches will be adequate to meet the running expenses.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE FUNCTIONS AND DISORDERS OF THE REPRODUCTIVE ORGANS, ETC. By William Acton, M.R.C.S., Etc. Seventh edition. 8vo, pp. xii, 263. Philadelphia: P. Blakiston, Son & Co., 1888. Price, $2.00.

Dr. Acton's work on the reproductive organs is too well known to need extended notice now. It contains a full and scholarly discussion of the normal phenomena connected with the function of the reproductive organs of both sexes, and of the disorders and abnormal exercise of these organs. It is a book full of wise counsels, and written in the spirit of a true moralist. It contains much that is interesting, and treats of a delicate subject in the most prudent manner. No attempt is apparent in it to attract readers by dwelling too long or too curiously on matters which are proper subjects for scientific investigation, but which cannot be dallied with without offending against chastity; and everywhere its tone is pure and its language carefully guarded.

There is no book which can well be compared with this one in the English language; and it is likely long to hold its position as a classic on the subject of which it treats.

The present edition is poorly printed—apparently from old stereotype plates, and has unfortunately no index.

FAVORITE PRESCRIPTIONS OF DISTINGUISHED PRACTITIONERS, WITH NOTES ON TREATMENT. Compiled, Etc., by B. W. Palmer, A.M., M.D. 8vo, pp. 256. New York: E. B. Treat, 1888. Price, $2.15.

It is rather the fashion with reviewers to abuse books of this sort; and, we confess, it was with no predisposition in favor of the class to which it belongs that we took it up. But justice requires the admission that a list of the prescriptions of men who have been successful in the practice of medicine may be very useful to men whose general notions in regard to treatment need to be put into definite shape before they can make good use of them. Such books as this have a legitimate field, and in their proper field they are not to be sneered at.

The volume before us has some merit. It would never do to follow its implied directions too blindly; but a judicious culling from its formulæ would probably help many a man in a strait.

In commenting upon it, it is hard to keep a just balance between commendation and warning; but the reader of it will have to exercise great caution lest what may be useful, if used wisely, prove a snare to his unwary feet.

DISEASES AND THEIR COMMENCEMENT. LECTURES TO TRAINED NURSES DELIVERED AT THE WEST LONDON HOSPITAL. By Donald W. Charles Hood, M.D., Cantab., Physician to the Hospital, etc. 8vo, pp. vii, 138. London: J. & A. Churchill, 1886. Price, two shillings sixpence.

This book consists of a series of five lectures on some points in pathology, symptomatology and therapeutics, delivered to nurses. All who have lectured to nurses upon elementary facts in medicine appreciate the difficulty of presenting these facts to them so that they will be of value in their practical work. The danger is that such necessarily incomplete information will spoil good nurses by giving them an exalted opinion of their knowledge of medicine. Dr. Hood has succeeded well, and nurses will be less likely to make this error after than before reading his book. The nature of the subject makes the lectures rather rambling, but they will prove interesting and instructive to nurses and the laity, and in some respects to physicians.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

213. The Treatment of Empyema: the Process of Repair, Etc. By G. J. Robertson, M.B., Oldham, England. From the *Medical Chronicle*, March, May, June and July, 1888. 60 pages.

214. The Anomalies of the Ocular Muscles. By George T. Stevens, M.D., New York. First Paper. From the *Archives of Ophthalmology*, 1887. 28 pages.

215. The Anomalies of the Ocular Muscles. Second Paper. By Geo. T. Stevens, M.D., New York. From the *Archives of Ophthalmology*, 1888. 33 pages.

216. Hot Water in the Management of Eye Diseases. By Leartus Conner, M.D., Detroit, Mich. 16 pages.

213. Mr. Robertson's pamphlet contains a complete and scholarly study of the conditions of empyema, and of the process of repair which takes place when different forms of treatment are carried out. It also contains a well described and well illustrated account of a method of subcutaneous drainage and irrigation which he has used with the best results in a number of cases. The pamphlet is of the most interesting and instructive character, and a careful study of it could not fail to be of advantage to all medical men.

214. Dr. Stevens, as is well known to the readers of the Reporter, attaches great importance to what some medical men have considered slight defects in the action of the muscles of the eyeball, and in the pamphlet before us he discusses the effects of such abnormal action—especially hyperphoria, and their treatment. In regard to the latter, he favors tenotomy, when this is practicable, and the use of prisms when an operation is not possible or desirable. He describes the method he follows, and the instruments he uses, the latter being illustrated with a wood-cut.

215. This pamphlet continues the discussion begun in pamphlet No. 214, in regard to the symptoms and treatment of certain abnormal conditions of the muscles of the eyeball. The symptoms are described with technical precision, and the treatment suited to different conditions is clearly stated.

216. Dr. Conner has prepared a very instructive paper on the use of hot water in diseases of the eye, such as blepharitis, corneitis and conjunctivitis, as well iritis and ophthalmia. The method of using hot water is fully and admirably described. This paper is not written so as to interest specialists alone, but all practitioners of medicine; and any physician who masters its contents will have gained information which will prove of service many a time in his experience.

CORRESPONDENCE.

Superfluous Hairs.

TO THE EDITOR.

Sir: Could you inform me of any safe and sure means of removing superfluous hairs from the face of a lady?

Yours truly,

H. J. STUBBS, M.D.

Wilmington, Del.,
Feb. 3, 1889.

[There is one way only of removing superfluous hairs, and that is by destruction of the papilla. Several methods for accomplishing this have been suggested from time to time. The most successful, and that at present employed by dermatologists, is by means of electrolysis. The operation requires a galvanic battery of ten to twenty cells, a needle-holder, and a fine needle. When done by a skillful and practised operator, the results are satisfactory, not more than ten per cent. returning. The operation is, however, tedious, and requires keen sight. The various details of this method may be found in all recent American works on dermatology.—EDITOR REPORTER.]

Result of a Herniotomy.

TO THE EDITOR:

Sir: In the REPORTER May 26, 1888, I reported an operation for radical cure of hernia. About that time the patient became entirely paralyzed on the left side, and he died yesterday morning. Ten hours after death, at the *post mortem*, I made a careful dissection of the site of operation. No person would have thought of there having been a hernia, except for the cicatrix left by the incision in the integuments. The opening through the conjoined tendon was entirely obliterated, being filled by dense connective tissue, which was strongly adherent to Pouparts ligament, the pubic bone and all the surrounding tissues, making that side much stronger and thicker than the opposite one. The spermatic cord and vessels were found in their proper canal. The internal abdominal ring had never been disturbed. Looking at the site of the hernia from the inside there was no depression, and nothing indicating a pathological condition, except adhesion of the peritoneum where the hernia formerly protruded. Those who saw it considered the result of operation perfect.

Yours truly,

A. ADY, M.D.

Muscatine, Iowa,
Jan. 22, 1889.

Father Damien.

TO THE EDITOR.

Sir: The statement made in your issue of Jan. 26, as to the condition of Father Damien dying of leprosy, has led me to think that possibly some of your readers may not know the history of this noble man in his self-sacrificing work. I therefore take the liberty of quoting the following utterance of Sir Risdon Bennett, M.D., made some two years since: "We cannot refrain from making reference to the case of the heroic Father Damien, which has excited so much painful sympathy. This young Belgian Roman Catholic priest, after his ordination in 1873, volunteered his services in the leper settlement at Malakoi, one of the Sandwich Islands. When he arrived there the lepers numbered 800, of whom between 400 and 500 were Romanists, and were dying from 8 to 12 per week. After ministering to these for 13 *years* (!), in every possible capacity, spiritual and temporal, as doctor, cook, carpenter, and even grave-digger, he has himself fallen a victim to the disease, and has resigned himself with the most touching Christian submission to all its well-known consequences, saying daily to God, '*Fiat voluntas tua.*'"

Yours truly, **

A Question of Etiquette.

TO THE EDITOR.

Sir: Suppose Dr. A. upon request of Mrs. B. attends her family in sickness during the year. Mrs. B. is the widow of a Doctor who died years ago, and whom Dr. A. never had any acquaintance with or even any knowledge of. Mrs. B. is a lady of affluence. Is there anything in medical etiquette which would make it improper for Dr. A. to make out a bill against the widow?

MEDICUS.

[If the widow in affluence were a person of proper feeling, it would not be necessary for our correspondent to ask this question. If she is not, there would probably be some risk of being abused if a bill were sent. But, as a matter of morals and of etiquette, it would be perfectly right to send a bill in such a case as is described.—EDITOR OF THE REPORTER.]

—Diphtheria is reported to be epidemic in Hancock county, Ohio. The schools in Big Lick, Blanchard and Marion townships have been closed, and others will have to be unless the progress of the disease abates. It is fortunately not of a malignant type, and deaths are few.

Notes and Comments.

The New Hypnotic, Sulphonal.

Constantin Paul spoke of sulphonal before the Therapeutic Society of Paris, Jan. 9, 1889 (*Bulletin Médical*, Jan. 13, 1889). After referring to the observations of Kast, which have been noted already in the Reporter, he said that when fifteen grains are given to a patient in the evening, he generally falls asleep in a half-hour, but sometimes only in an hour or two. The sleep is light and without either dreams or night-mare, and is followed by a feeling of comfort without gastric uneasiness on awaking.

Sulphonal is especially indicated, he says, in nervous insomnia, in doses of fifteen or thirty grains. M. Paul has employed it with variable success in toothache, in a case of cellulitis of the face complicated with neuralgia, after a fracture, in alcoholic delirium, delirium tremens, in mania, in hypochondria, and in acute diseases, fevers, etc. Sulphonal, he says, may be substituted for morphine; thirty grains produce sleep in morphinomaniacs. In a case of hypertrophy of the heart no intolerance was produced; the cardiac distress was not increased, respiration remained quiet. He regards sulphonal as an adjuvant in rheumatism when the pain has been previously allayed with salicylate of soda; so also in acute or subacute bronchitis. In the latter he first allays sensibility with codeine and then obtains restful sleep with sulphonal, which he says is well borne even by children.

M. Huchard was more guarded in his statements. He gave a brief account of fourteen cases in which he had employed it; in five of them it was unsuccessful. He stated that sulphonal has no anæsthetic power. Its greatest action is produced in nervous insomnia and is prolonged for four or eight hours, rarely longer, although Kiffer has observed a patient in whom sleep lasted thirty-six hours. Because of its slow action it is necessary to give at the outset a large dose. It sometimes occasions slight diuresis. Its principal inconvenience is its being followed by a painful awaking, with a feeling of hesitation in walking, resembling cerebellar tottering rather than ataxia. Some eruptions and hallucinations of hearing have also been noted. If sulphonal is a substitute for chloral, he says, it is not superior to it, its only advantage being its prolonged action.

Treatment of Baldness.

Dr. Lassar has a communication on the treatment of the hair in the *Therapeutische Monatshefte*, Dec., 1888. He regards alopecia as a parasitic disease, and he recommends an antiparasitic treatment which has commended itself in more than one thousand cases. The scalp should be soaped by an expert hand for ten minutes daily for the first six or eight weeks, later less frequently. For this purpose a strong tar soap is best. After the scalp is well lathered the soap is carefully washed off with tepid followed by cool water, contained in an irrigator or watering-pot. The washing with cool water hardens the scalp in a happy manner against the colds to which patients with alopecia are usually disposed. The scalp is then dried gently and rubbed with:

Sol. hydrarg. bichlor. . . .	gr. viiss to f℥iv¾
Glycerini,	
Spir. Cologn.	āā f℥iss

It is then dried and rubbed with absolute alcohol, to which one-half per cent. naphthol has been added; and then as much of the following as possible is rubbed into the scalp, which is now quite free of fat:

Acidi salicylici	gr. xxx
Tinct. benzoini	♏ xlv
Olei pedum tauri (neat's foot oil)	ad f℥ iii

The soaping removes all adherent substances, the sublimate solution is readily absorbed by the mouths of the hair follicles, the alcohol dries the scalp, removes the fat and disinfects it, and finally the mixture of salicylic acid and oil is taken up by all the pores and exerts its action in the interior of the glands.

A daily use of this treatment will bring about a favorable result in the majority of the cases. This is especially true in the cases of young women and girls. The brittle, lustreless hair becomes flexible and elastic. Hundreds of new, vigorous hairs shoot up. —*Wiener med. Presse*, Dec. 23, 1888.

Regeneration of the Hair.

In the *Semaine Médicale*, Nov. 28, 1888, Besnier recommends the following treatment for alopecia: The neighborhood of the bald spot is shaved, or the hairs which come out easily are removed, and an application is made of a mixture composed of equal parts of chloroform and glacial acetic acid. This mixture has caustic properties, and must be applied lightly with a camel's hair brush each evening; and if the bare spot be large only part of it can be treated at a time, or too much pain will be caused.

The Transmission of Leprosy.

Amongst instances which have lately been published which tend to show that leprosy is communicated by contagion, none are more striking than those which have been related by Dr. Zuriaga in the *Annales de Derm.*, vol. ix, No. 6. In 1849 leprosy did not exist in the village of Parcent, in the province of Alicante. In 1850 a leper, from the neighboring town of Sagra, in the province of Alicante, district of Pego, came to reside in Parcent with one of his intimate friends, Vincent Poquet Andres. The two friends ate from the same plates, with the same spoons, drank from the same glasses, and slept together. The effects of these close relations were not slow in making themselves evident. In the first year Poquet had acquired the leprosy which infected his friend. A nephew of Poquet, called Ramont Poquet Perez, who frequented the house of his uncle, was not long in becoming affected. Ramont had three married brothers, Baptiste, Joseph and Rosa. Fearing contagion, Baptiste and Rosa ceased to have any relations with Ramont. Less careful, Joseph and his children continued to have communication with him. Soon afterward leprosy became apparent in the house of Joseph. He had seven children; five of them were attacked. The two others were so impressed by this fact that they left their father's house, established themselves elsewhere, and ceased to have any relations with their family. They have remained free from leprosy. Joseph Perez died of disease of the heart. His wife still lives and is free from leprosy. The five sons who were leprous are still alive, and have reached the period of exhaustion. Joseph Mora lived close to the first leper in Parcent, being an intimate friend of Vincent Poquet. Soon afterward he developed leprosy. Joachim Guier, a friend of Mora, also became a leper, and some years later his two brothers were also attacked. They lived in the same house. Without following Dr. Zuriaga's paper further in detail, suffice it to say that two sisters appear to have been infected by Guier, and that shortly afterward their five brothers were in their turn attacked. Of five young soldiers more or less associated with Ramont Perez, three avoided him, and two were careless as regards contagion. The three remained healthy, the other two became lepers. Soon afterward other inhabitants of the village became lepers. Without there being apparent cause of contagion of late years, a considerable part of the population has become lepers. Since 1850, in this small village, there have been about sixty cases of leprosy; forty-five of these lepers have died. According to the statement of the Mayor of Parcent, by whom these facts have been communicated, fifteen are still alive.—*British Med. Journal*, Jan. 12, 1889.

Treatment of Typhoid Fever with Naphthalin.

Dr. Gennaro Petteruti communicates his experiences with naphthalin in the treatment of typhoid fever to the *Giornale internaz. delle scienze mediche*, No. 10. Naphthalin is borne by the organism in doses up to sixty grains daily without noteworthy disturbance. The only disturbances caused by it when introduced into the stomach are a brownish coloration of the urine and more or less severe pains on micturition. The brown color of the urine begins five hours after administration of the drug and lasts during the whole course of the treatment; it is due to resorption of small quantities of naphthalin by the bowel and their excretion in the urine. The pain on micturition is also produced by the presence of naphthalin in the urine. Diarrhœa was observed rarely.

Naphthalin, he says, exerts not only an antipyretic action analogous to that of antipyrin, thallin, and the usual antipyretics, but it also has a direct healing influence upon the typhoid fever. In Petteruti's cases the fever ceased upon the administration of the naphthalin and did not return, even when the drug was no longer given. The fall in temperature, which begins after two or three days' treatment, proceeds until the fever completely disappears. The healing, or better, the abortive action, of naphthalin is explained by its direct influence upon the chief seat of the disease. It is to be preferred to other antiseptics because it is well borne by the mucous membrane of the bowel, is absorbed only in very small quantity from the intestine, and therefore remains longer in contact with the diseased part upon which it exerts its action.

In children under four years of age, Petteruti began with fifteen grains, and never exceeded thirty grains a day. Adults received on the first day seven and one-half grains four times daily, given at intervals of an hour, and increased on the following days up to seven or eight hourly doses of seven and one-half grains.—*Wiener med. Presse*, Jan. 6, 1889.

Antipyrin in Obstetric Practice.

Dr. Talbot Jones, of St. Paul, Minn., communicates an interesting article on antipyrin in obstetric practice to the *Northwestern Lancet*, January, 1889. He has employed antipyrin in seven cases of confinement with the very happy effect in six cases of subduing the labor pains without checking the contractions of the uterus. He injects from twenty to thirty grains into the rectum, and repeats the injection if it is necessary. This treatment has also been used in two cases of inevitable abortion, one probably due to syphilitic degeneration of the villi, the other to causes unknown. In both cases, the ovum was thrown off without suffering by either patient, after one or two rectal injections of antipyrin.

In concluding his paper, he remarks that its anodyne effect is probably due to the quieting action exerted upon the spinal nerves supplying the uterus. That it lowers reflex irritability, and markedly dulls, where it does not wholly abolish sensibility, must be patent to everyone who has prescribed it in other conditions, as, for example, hemicrania, neuralgia, migraine, the darting pains of locomotor ataxia, *crises gastriques* with shooting pains in the legs, and in that large and varied class of nervous disorders in which sensibility is affected.

Clinical Experiences with Sulphonal.

Mr. Conolly Norman, Medical Superintendent of the Richmond Asylum, contributes an interesting paper on sulphonal to the *Dublin Journal of Medical Science*, January, 1889. He has employed it in twenty-two cases, and summarizes his experiences as follows: 1. Out of the twenty-two persons observed, in only two were any bad results noticed. These were specially unfavorable cases, and cases in which other sedatives had failed. 2. In no case was gastric or intestinal trouble observed. 3. In eight cases refusal of food, or a tendency thereto, existed. This was overcome, and the appetite seemed to improve under the use of sulphonal. 4. In six cases masturbation and tendency to sexual trouble existed. The drug appeared to lessen the tendency to self-abuse and erotic excitement. 5. In some recurrent cases it appeared to check or shorten the attack. 6. Out of the limited number of cases treated the majority happened to be melancholiacs, but the drug seems to exercise a hypnotic and sedative effect in various forms of insanity. 7. No patient complained of the drug, or refused it for other reasons than delusional ones. 8. Sleep produced appeared to be natural, refreshing, and undisturbed by dreams.

In comparing sulphonal with other medicines having similar effects, it is needless to refer to the products of opium, or to chloral. Of the more modern drugs paraldehyde is, perhaps, the most used. Its great disadvantage is that it requires constant increase in the dose. As far as Mr. Norman is able to judge, this does not apply to sulphonal. Paraldehyde long continued is also stated by Fröhner to cause destructive changes in the blood corpuscles, while Krafft-Ebing points out that it occasionally produces symptoms resembling alcoholism. Urethan, to which Mr. Norman has given a pretty extensive trial, he declares to be uncertain, and of no great strength. Amylene hydrate is uncertain and dangerous, as Schlöss's cases prove (*Jahrbuch der Psych.*, VIII., 1 and 2). Methylal is liable to the same reproaches. Hypnone, he says, is undoubtedly of some value; he once thought highly of it, but has found it uncertain, and it appears indisputable that patients soon become habituated to its use. All the three last-named drugs, he says, are so abominable in taste and smell that it is almost impossible to get patients to swallow them, and, as might be expected from this, they all upset the stomach.

The advantages of sulphonal he states to be: 1. It is absolutely free from smell. 2. Otto states that it leaves on the mouth a faint bitter after-taste. This Mr. Norman noticed, but it is very slight, and patients always say it is tasteless. 3. It produced, in his cases, no gastric derangement, and no troublesome head symptoms; it does not affect the appetite. 4. The sleep which it produces is relatively "natural."

Its disadvantages are: (1) that it is bulky and practically insoluble, therefore difficult to administer; and that, perhaps owing to its insolubility (2), it is slow in action. A further practical disadvantage hitherto has been its very high price.

Mr. Norman quotes Otto to the effect that in a few of the sixteen cases in which he used sulphonal solely as a hypnotic—*i. e.*, giving a single dose at night—a slight degree of giddiness and unsteadiness, with a sense of weariness, was experienced next morning. The same phenomena occurred in some of Rosin's and Schwalbe's cases. Otto gave the drug with excellent effect as a calmative, in small and repeated doses during the day, in nineteen cases. He observed

not only the head sensations referred to, but the occurrence of transient digestive disturbances—vomiting and slight diarrhœa—in less than half his cases. These troubles soon passed off, though the drug was continued; and he notes that in most cases the appetite was good. Schwalbe observed in some cases similar digestive troubles, but attributed no consequence to them. Funaioli and Raimondi, who appear to place sulphonal at the head of the list of hypnotics, have observed no unpleasant after-consequences. Cramer, writing in June, 1888, as the result of Rabbas's and his own experiments, conducted on forty-nine patients, could record no unpleasant consequences save an occasional slight drowsiness on the morning after a dose.

Mr. Norman has no doubt that unpleasant and even injurious results will be found to occur from the injudicious or continual use of sulphonal, and that it will be found to have its peculiar dangers, like every other potent drug. The use of any drug to procure sleep or rest must at best be regarded as a deplorable necessity, and dangers should be apprehended from what must always be, to some extent, a blind interference with natural laws. It would seem, however, that we are justified in saying that in sulphonal we possess a powerful and not disagreeable hypnotic, free from any immediate danger, and followed by very trifling, if any, unpleasant after-effects.

Treatment of Thrush.

Dr. F. Forscheimer takes up the symptomatology and treatment of stomatitis mycosa, or thrush, in the *Archives of Pediatrics*, Feb., 1889. Prophylaxis, he says, is as important as the treatment proper. All slight abrasions may become infected with the parasitic cause of the disease, the saccharomyces albicans. The mother or nurse should be taught how to keep the nipples clean, and how to cleanse the mouth of the infant. The best disinfectant for the feeding utensils is exposure to the temperature of boiling water for a little while. Every part of the apparatus should be so arranged that the boiling water can gain access to it, and that any deposit can be removed mechanically. When this is rigidly carried out, infection becomes impossible even in hospitals.

The treatment proper consists of two parts: the mechanical removal of the fungus, and its destruction. To accomplish the first, the attendants must be told to wash out the mouth at stated times—for instance, between the times of nursing and immediately after nursing. For this purpose, a solution of one drachm of bicarbonate of soda to a tumbler of water is very serviceable. The remedies used must be applied four or five times daily, with a brush. He avoids syrups. In his own experience, he has rarely found it necessary to use anything except sodium bicarbonate. Occasionally, when ulcers are produced, it becomes necessary to touch them with nitrate of silver; but in uncomplicated cases this is exceedingly rare. There are some cases, he says, which will resist any or all methods of treatment.

Calomel in small doses or corrosive sublimate very much diluted almost always acts as a specific in intestinal troubles which are due to thrush. But the relation between intestinal troubles and thrush must always be kept in mind, and the indiscriminate use of cathartic alkalies or other laxatives must be prevented as doing the patient more harm than good, reducing his strength and being absolutely harmful and needless. Baginsky, he says, claims good results from resorcin, and warns against the use of too large a dose (from one-half to one per cent. solution—never more than one teaspoonful every two hours). But Dr. Forscheimer does not see how this, or any other remedy, can produce an effect upon an œsophagus stopped up completely with plugs of parasitic growth. When a conjectural diagnosis of œsophageal thrush has been made, he regards it as most expedient to introduce the soft catheter into the œsophagus. In one case, he succeeded in gradually working his way into the stomach with a catheter; some of the masses were pushed into the stomach and were then removed by vomiting. The patient, however, died a few days afterward, and post-mortem examination showed that the œsophagus had been again filled up.

"Semelincident" Diseases.

The *Pittsburgh Med. Review*, Jan., 1889, says that no medical word at present expresses the fact that certain diseases occur only once in the individual—disorders, such as small-pox, in which one attack usually confers immunity from subsequent infection. Prof. R. E. Williams, of Allegheny, has suggested a new term descriptive of this class of maladies. It is "semelincident," from the Latin *semel*, once only, and *incido*, to happen or occur. The word appears to be a useful one; it has the added merit of being properly formed and is worthy of adoption.

Treatment of Syphilitic Disease of the Eye-lids.

P. Silex states in the *Deutsche med. Wochenschrift*, No. 43, 1888, that the best method of treatment of syphilitic disease of the eye-lids is a sweat "cure" combined with inunctions and followed by the use of about two hundred grains of iodide of potash. Injections of corrosive sublimate and of calomel do not give correspondingly good results. Fourteen patients who had been treated with injections of corrosive sublimate acquired specific disease of the eye in one and one-half years at latest; while of fifty others who had neglected their syphilis up to the outbreak of the eye disease, but then underwent the treatment first mentioned, twenty-five remained free from any symptoms whatsoever for at least one and one-half years; the remaining twenty-six in part had slight relapses and in part had withdrawn themselves from control. In the interstitial keratitis that is frequently associated with hereditary syphilis, the best results were obtained with iodide of potash. To avoid errors in estimating the results effected by a drug, Silex cautions against assuming that every eye affection occurring in a syphilitic is in causal connection with syphilis.—*Centralblatt f. d. med. Wissenschaften*, Jan. 5, 1889.

A European View of the "Pneumatic Cabinet."

Dr. Moeller, of Brussels, who has, according to the preface of his little pamphlet, "Un Mot sur L'Aérothérapie," had considerable experience in the use of compressed and rarefied air, says concerning the "Pneumatic Cabinet" practically the same thing that Solis-Cohen, Platt and others in this country have consistently maintained. "The procedure of Dr. Williams," says Moeller, "possesses no novelty except the name, which appears to be indeed very happy. How does it in fact work? The patient is placed in a partial vacuum, but he continues to breathe air at the ordinary pressure, impregnated with some medicament. In other words, the air of bronchi and lungs is in communication with an atmosphere *relatively compressed* and charged with antiseptic vapors. . . . The procedure of Dr. Williams produces the same result as the portable apparatus of Waldenburg and others with this sole difference—which however is not to the advantage of the new procedure—that Dr. Williams obliges the patient not only to inspire air relatively compressed, but also to make expiration into the same air, while with the portable apparatus, expiration is made into the free atmosphere. It is indeed true that Waldenburg at first essayed equally to make this twofold use of compressed air, but in view of its disadvantages he was not slow to abandon the practice." . . . "What is the advantage of medicating the air? The practice has been long since thoroughly tested and abandoned as well at Berlin by Waldenburg as at Brussels by Tamin-Despalles and his successors. We ourselves have repeated the same efforts both with pneumatic chambers and portable apparatus. We have at last fully recognized the perfect inutility of the combination of the two methods (inhalations of compressed air and of medicinal substances) and are convinced that it is far preferable to submit the patient to aërotherapy alone, and if indications for medicamentous inhalations are presented to administer them separately by means of vaporizers, or atomizers, or respirators constructed for that special purpose."

"The method of Dr. Williams, then, offers nothing new from the double point of view (aërotherapy and inhalation), and experience has demonstrated that it is of no advantage to employ simultaneously the two therapeutic procedures."

Purpura from Iodide of Potassium.

M. Besnier has recently had an old syphilitic as a patient, who showed a remarkable intolerance to iodide of potash, which produced a purpuric eruption upon the lower limbs each time he took it. M. Besnier had made him take five drops of tincture of iodine. The patient was seized with symptoms of idism—dyspnœa, anxiety, acceleration of pulse—to such a degree that the iodine had to be stopped; but he had no purpura. It seems, therefore, that iodic purpura is not produced after the employment of iodine, but only in patients who take iodide of potassium.—*Gazette Hebdomadaire*, Jan. 18, 1889.

Remedy for Erysipelas.

Dr. W. L. Schadkewitsch records in the *Medozinskoie Obosreny*, No. 12, 1888, that he has found a mixture of equal parts of ammonium-sulphoichthyolicum and lard an admirable application in erysipelas. The effect of its use was to shorten the duration of the disease, and to dissipate remarkably soon the burning pain.

Cirrhosis of the Liver in Cats.

Professor Greenfield reports in the *Journal of Comp. Pathology*, Dec., 1888, the results of his examination of two well-marked examples of hepatic cirrhosis in cats. In the one specimen the organ was much enlarged and smooth, resembling to the naked eye a leucocythæmic liver. Microscopically, however, the lobules were found to be separated by wide bands of connective tissue, within which were dense plexuses of young bile ducts and bile capillaries, the formation of which appeared partly to be by fission of the liver cells. In the other case, a successful injection of the bile ducts revealed a large number of such plexuses, and a comparison with a healthy liver proved that in the cirrhotic the plexuses were of new formation. Each animal had ascites, and the cirrhosis was monolobular. Professor Greenfield points to the similarity in anatomical character between the conditions here found and those met with in hypertrophic or "biliary" cirrhosis, the difference being that in these cats there was no evidence of obstruction of the duct, or any jaundice, whereas there was marked ascites. In man hypertrophic cirrhosis is characterized by pronounced jaundice, and ascites is usually absent or is slight.—*Lancet*, Jan. 12, 1889.

Athletic Sports and Scholarship.

The Phila. *Ledger*, Feb. 1, says that Prof. Richards, of Yale College, has made a study of the records of 2425 students in order to determine, if possible, the relations of athletics, in Yale, to scholarship. The general result is that the athletes fall slightly behind the non-athletes in scholarship, but not so much as to demand a suppression of such exercises. In some branches of athletic exercises the students who engage in the sports are above the average of the non-athletes in scholarship. For the slight difference noted between the two great classes, there may be greater strength and endurance or physical development compensating for the loss of scholarship. This does not appear from the report, but a healthy, energetic man with fair scholarship is a better product of college education than a debilitated student with higher average in book studies. So far as statistics go, however, the most that can be claimed for Prof. Richards's report is that it is negative in its results, and shows that athletic games do not seriously interfere with the scholarship of students.

Saccharin.

A commission appointed by the Belgian Academy of Medicine has come to the conclusion that saccharin cannot be considered a substitue for sugar in foods; but that, although differently borne by different persons, it is not poisonous. They are of opinion also that it is not wholly excreted by the kidneys, but is liable to find its way into the milk and saliva. Consequently the commission has reported that in its judgment all persons selling wholesale or retail articles sweetened with saccharin should be compelled to indicate the fact in a conspicuous manner.—*Medical Press and Circular*, Jan. 9, 1889.

Prophylaxis in Cerebro-Spinal Meningitis.

The Berlin police intend to issue the following regulations to prevent the spread of cerebro-spinal meningitis: 1. Every physician shall at once report to the police any case that comes to his knowledge. 2. Patients are to be isolated. 3. The children of families in which there are cases are to be kept from school. 4. The sick rooms, expectorated matter, linen, handkerchiefs, clothes, and other belongings of the patient used during the illness are to be cleaned and disinfected.—*Lancet*, Jan. 5, 1889.

A Gallant Act.

It is our pleasant duty, says the *British Med. Journal*, Jan. 5, 1889, to record another of those acts of heroism on the part of Army Medical officers, which are so often displayed under circumstances of peculiar difficulty and danger. The facts, as given in the *Civil and Military Gazette*, of Lahore, show that on November 4, during the Black Mountain Expedition, when our troops were retreating, one man was severely wounded and placed on the shoulder of a comrade, who, however, was soon exhausted; Surgeon Heuston then took the man on his own back and conveyed him, under a heavy fire of shot and rock from the enemy, to a place where the troops were forming, and where a stretcher could be procured.

—For the week ending Feb. 2, the Sanitary Bureau of the Health Department of New York City reports the following numbers of cases of contagious diseases and deaths: Typhoid fever, 6 cases and 2 deaths; measles, 324 cases and 21 deaths; diphtheria, 178 cases and 39 deaths.

NEWS.

—Dr. N. F. Bosley died in New York City, Feb 10. He was a surgeon in the navy during the late war.

—A man in Mt. Vernon, New York, on Feb. 4, took strychnine supposing it to be quinine, and died in a short time.

—A despatch from New Brunswick to the daily papers states that cerebro-spinal meningitis prevails in that region, and is said to be spreading.

—The *North Carolina Med. Journal,* Jan., 1889, states that a call has been sent out for a Sanitary Convention to be held in Raleigh, N. C., Feb. 6, 1889.

—It is stated by the *Lancet,* Jan. 5, 1889, that the professors at the University of Tomsk have given up the whole of their first half-year's fees for the benefit of the students, nearly all of whom are poor.

—Emin Bey has been commonly spoken of as Dr. Schnitzler, an Austrian; but a gentleman living in New York, and who claims to be a first cousin of Emin, says his name is Dr. Edward Schnitzer, and that he was born in Prussian Silesia.

—Press despatches state that at the fire in the hospital at Madrid, on Feb. 7, the helpless sick were carried out by doctors and nurses, the Governor himself removing several who were suffering from contagious diseases, and not a life was lost.

—The *British Med. Journal,* Jan. 26, says: Dr. W. R. Gowers, F.R.S., has resigned the appointment of Physician to University College Hospital. We believe that the motive which has prompted Dr. Gowers to take this step, which will be felt to involve a serious loss to the teaching power of University College, is that he finds himself unable to meet, with impunity, the increasing claims of consulting practice, and at the same time to perform the duties of Professor of Clinical Medicine and of Physician with the regularity which is desirable at an important medical school. While relinquishing the more arduous post, however, he retains his appointment as Physician to the National Hospital for the Paralyzed and Epileptic, Queen Square. Dr. Gowers possesses qualities as a clinical teacher in nervous disease which could ill be spared, and his retention of the last-named office will enable him to continue the "clinical afternoons" at Queen Square, which have become so well known to medical visitors and senior students in London.

HUMOR.

THE DRUGGIST charges the soda fountain and makes the customer pay cash.—*Providence Journal.*

RELATIONS between a milkman and a millionaire are naturally strained. —*New Orleans Picayune.*

A HORSE in Dakota has eight feet. He must be the "Lost Cord" we heard sung about so much.—*Lowell Courier.*

MRS. PALLID—"Don't you find that the noise of the boiler foundry across the street affects your nerves, Mrs. Youngwife?"

Mrs. Youngwife—"I seldom hear it."

"How strange!"

"Well, you see, baby is teething now."—*Drake's Magazine.*

DR. BUSHY, whose figure was beneath the common size, was one day accosted in a public coffee room by an Irish baronet of gigantic size, with "May I pass to my seat, O giant?" The doctor, politely making way, answered, "Pass, O pigmy." "Ah, sir," replied the Baronet, somewhat nettled, "my expression alluded to the size of your intelligence!" "And my expression," said the doctor, "to the size of yours."—*Lancet.*

OBITUARY.

JOSEPH S. LUSK, M.D.

Dr. Joseph S. Lusk, of Butler, Pa., died Feb. 2 of heart disease. He had been seriously ill for several months and his death was not unexpected. Dr. Lusk was the oldest son of Dr. Loring Lusk, who was one of the earliest settlers in Harmony, Butler county, and died a few years ago at a great age. The son chose his father's profession and studied medicine at the Western Reserve College, Cleveland, O., in 1850, and soon after began practising in Harmony. In 1886 he went to Butler, where he soon came into a very extensive practice, and was beloved for his talent, learning and unaffected ways. During his life of 63 years Dr. Lusk, besides pursuing a successful professional career, found time for extended reading, study and other pursuits. He was a member of the State Legislature for three terms and held various local offices. He was at the time of his death a member of the Pension Board for the Butler district, and had held numerous offices in medical societies. He was an enthusiastic geologist and mineralogist and had many rare and curious specimens.

EFFERVESCENT SPECIALTIES

WM. R. WARNER & CO.'S
TRIPLE
(Effervescent)
BROMIDES

Advantages:—Useful in Headache, Nervousness, Sleeplessness, Migraine, Diurnal Epilepsy, Etc.

℞ Sodium Brom. grs. 15.
Potassium Brom. grs. 10.
Ammonium Brom. grs. 5.

Administer one teaspoonful in half a glass of water. Drink while effervescing. In Diurnal Epilepsy take a dessertspoonful three times daily until sense of taste is partly destroyed; after this reduce the frequency of dose, but keep the fauces in a benumbed condition.

WM. R. WARNER & CO.'S
CHALYBEATE
(Effervescent)
SALINE
(Ferric Saline Effervescens, Dr. Means)

℞ 1 gr. Citro-tartrate of Iron and 20 grs. of Soda.

Dose.—A heaping teaspoonful of the salt, containing 1 gr. Citro-tartrate of Iron and 20 grs. of Soda, to be taken in a glass two-thirds full of water and drunk while effervescing. If a more decided effect is desired, warm instead of cold water may be used. In all cases this draught should be taken but once or twice a day, and then on an empty stomach, preferably before breakfast. No restrictions as to diet. One or two Pil. Digestiva (W. & Co.) may be taken at noon, before eating, as a dinner pill.

WM. R. WARNER & CO.'S
(ANTIPYRINE ET SODIUM SALICYLATE)
ANTALGIC
(Effervescent)
SALINE

℞ Antipyrine, 4 grs. Salicylate of Soda, 4 grs.
In each dessertspoonful.

Dose.—One dessertspoonful, to be repeated as often as the case may require. Almost a specific in Neuralgic Headache. Prescribed in all cases where Antipyrine is used, with more better and more certain results.

WM. R. WARNER & CO.'S
APERIENT
(Effervescent)
SALINE

A pleasant and excellent aperient and refrigerant, very acceptable to the stomach. Given in all cases indicating the need of an active aperient, and to be given daily to all patients under treatment with Dosimetric therapeutics. (See Wm. R. Warner & Co.'s Dosimetric Granules.)

Dose.—One tablespoonful in half a glass of water.

PREPARATIONS SUPPLIED BY ALL LEADING DRUGGISTS.

☞Samples of the above Salts furnished upon request.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

STOMATITIS GANGRENOSA; A NEW TREATMENT.

BY LLEWELLYN ELIOT, M.D.,

WASHINGTON, D. C.

In selecting "Stomatitis Gangrenosa; A New Treatment," as my subject, I do so in the hope that my success in the treatment of my cases, will encourage others to give the plan a trial. At the outset I shall state my position and belief in a few words, and then endeavor to sustain them.

Stomatitis gangrenosa is dependent for its existence upon a germ, a parasite, a fungoid growth; the corrosive chloride of mercury has the power, when employed in sufficiently strong solutions, of destroying germs and parasites, therefore the application of this germicide is the correct treatment of this disease.

A few observations upon this affection will not be amiss. Dr. Battus, a Dutch physician, gave the first correct description of this disease, as far back as 1620, in his "Manual of Surgery." Since then various writers, Swedish, French, English, American and German have described it as water kanker, noma, gangrene of the mouth, gangrenous scorbutus of the gums, necrosis infantilis. In America, the best articles on this subject are by Gerhard, Coates, Meigs and Pepper, and Cohen. This is not a disease of private practice nor is it frequently seen in hospital or asylums. It attacks children between their first and the sixth years, as a rule, and those older as the exception. Only those children who are constitutionally run down by long and severe illness, by improper feeding, by unsanitary surroundings or the various concomitants of the poorer classes, are affected by it. Although not considered a contagious affection, I believe that one case of gangrenous stomatitis, admitted into an asylum for foundlings and not subjected to restriction, such as isolation and the use of special towels, cloths, clothing and bedding, will prove the starting point for an epidemic

of this disease. I write this from firm conviction and, I think, from the point of view of experience.

The disease sets in without special symptoms and may so escape detection, although there is a gangrenous odor to the breath. The mucous membrane ulcerates and the cheek or lips become tumefied, shining, pale and hard, and the disease may either spread externally or follow the mucous membrane of the mouth, perforating the cheek or laying bare the alveolar processes, or even an entire section of the maxilla, superior or inferior, with subsequent necrosis. The patient's strength does not fail, unless the previous condition of debility increases. Death supervenes in the second week, either from entero-colitis, pneumonia, pulmonary gangrene, or collapse. When recovery follows it is only with loss of much tissue and with more or less deformity. The diagnosis is easy, for the odor of the breath and the appearance of the eschars are sufficient to set aside all doubts as to the nature of the affection. The death rate is stated at from seventy-five to eighty-five per centum, but is less in private practice than in hospital or asylum practice, and as a matter of course depends somewhat upon the simple or complicated condition of the case.

As to the treatment, I believe that the internal administration of chlorate of potash with the tincture of the chloride of iron, sulphate of quinine, stimulants, and the local application of caustics, is the only treatment worthy of mention. As to caustic applications to the diseased parts, hydrochloric acid is preferred, although nitric acid, the actual cautery, acid solution of nitrate of mercury, and undiluted carbolic acid are employed. Gerhard employed undiluted tincture of the chloride of iron, Maguire uses the subnitrate of bismuth. Condie used sulphate of copper, thirty grains to the ounce of water. As an application, my preference is decidedly in favor of the corrosive chloride of mercury in strong solution, and my prescription is:

℞ Hydrargyri chloridi corrosivi . . gr. j
Aquæ destillatæ . . . . . ℥j

M. Sig. Apply with a cotton probang twice a day if necessary to remove the eschars.

These applications are to be made twice a day if necessary; if the eschar is removed and no further extension of the disease takes place, then there is no further need for such a strong solution. I then make a solution of 1 to 2000 and continue its use as a wash until the suspicious appearance of the ulcer has left, when a solution of tincture of myrrh is employed. To be effective any application must be thorough and be repeated as long as there is any evidence of the continuation of the disease. Internally, I order:

℞ Potassii chloratis . . . . . ℥iss
Tincturæ ferri chloridi . . . . . f℥j
Aquæ destillatæ . . . . . f℥ij

M. Sig. Teaspoonful every three (3) hours.

In reviewing the experience of the past fifteen years, I find that I have treated five cases of stomatitis gangrenosa, two of which rapidly went to a fatal termination, the other three recovering after a long convalescence. In treating these cases the approved methods of procedure were faithfully and religiously followed in two cases. The nitric acid applications were made without fear, chloride of iron and chlorate of potash were administered to the point of tolerance, quinine and alcoholics were not spared, but both the patients died in spite of the care and treatment they received. The three remaining patients were treated with free applications of the corrosive chloride of mercury in strong solution, with the iron, the potash, the quinine, the stimulation and the full diet of the other two, and they recovered from the disease. The eschars separated much sooner than when the acid was employed. In each of these cases there was a relaxed condition of the bowels, which was controlled with paregoric.

I am not a believer in the antiseptic treatment and methods of the day, for I do not think they are applied in sufficient strength, and I do not believe that a douching, an irrigation, a washing, a spraying—call it what you will—with a quart, a gallon, yes, a barrel, if needs be, of a solution of the corrosive chloride of mercury, of a strength of 1 to 3000 or 1 to 4000, will do as much good as the same douching, irrigation, washing, or spraying with clean water. With this belief, different as it is from that of the majority of my professional brethren, I employ the very antiseptic I decry. Compare the difference in strength, and then see "the faith that is in him." Not for one moment do I doubt the records of experimenters in this line of study, nor the favorable reports following the use of such weak solutions; but I still assert, that to get the germicide effects of the corrosive chloride of mercury, it must be employed in very strong solutions.

THE CLIMATIC TREATMENT OF PULMONARY CONSUMPTION IN THE DRY ELEVATED REGIONS OF THE ROCKY MOUNTAINS.

BY L. HUBER, M.D.,
ROCKY FORD, COLORADO.

Each year develops fresh discussions of the climatic treatment of pulmonary consumption. In these discussions there is much difference of opinion and teaching as to what part altitude takes in the treatment of the disease; some advocate its beneficial effects, others deny them. Another matter of contention is as to the aseptic qualities of the atmosphere in many parts of the region specified. This condition is little understood by physicians outside the limits in question, and hence is overlooked in the discussions of the present question. That an old and thickly settled region, into the atmosphere of which the smoke, dust, and effluvia of long years have ascended, should differ in the amount of "atmospheric dust" and in its quality from that of a comparatively recently settled country, is quite reasonable. In truth, the fact has been demonstrated by scientists and observers. What relation this condition of the atmospheric air should have to the climatic treatment of consumption will subsequently receive due consideration, it being sufficient now to mention simply the fact of such a difference of air, and to note that in the present inquiry it is often disregarded.

Another source of disagreement among physicians on this subject is the misleading views and erroneous notions entertained as to the bodily temperature changes in pulmonary consumption. Let us briefly discuss this subject and remove its obscurities. Dr. Williams, in his masterly work on "Pulmonary Consumption," by innumerable clinical observations, substantially concludes as follows: The active deposit of tubercle (tubercularization) produces an irritative condition of the system and increases the heat-producing functions. But tubercularization, in taking hold of the system, produces a tendency to collapse. Now, the changes of bodily temperature, wherever present, are the resultant, as it were, of these two opposite conditions. To quote the exact words of the author: "To understand the temperature chart of phthisis, we must bear in mind that it is due to two principal agencies:

"1. Excessive action of the processes by which the heat of the body is maintained, the processes of oxidation and disintegration, combined with a weakening of the inhibitory action of the nervous system in these phenomena, such as is present in all inflammations and fevers.

"2. A collapse of the constitutional powers, which characterizes the natural course of consumption. These two influences act on the patient, and according as one or the other predominates, is shaped the course of the temperature. When they are equally balanced, a chart hardly differing from the normal, results. When collapse prevails, subnormal temperatures appear, and, when inflammatory processes are in the ascendent, pyrexia shows itself."

This teaching is essentially different from that propagated in many text-books on practice, and that entertained generally by medical men. It contradicts the erroneous notion that the temperature rise in phthisis is commensurate with the extent of tubercularization.

Having a proper conception of the temperature changes attending the active deposit of tubercle in the lungs, or coincident with the primary changes in phthisis, let us examine whether these have the same cause as the febrile phenomena attending softening and extrusion of tubercular masses, during the later stages of the disease. That the latter depend upon other conditions, is beyond dispute. There is now some absorption of septic matter and consequent irritative or hectic fever. Dr. Williams supports this view with observations upon many cases, but our common text-books fail to make this distinction.

We are now prepared to analyze to advantage the relation of pulmonary consumption to the climatology of the Rocky Mountain regions. If the climate of this region, with the effects of elevation, tends to make the system more tolerant of tubercularization and to limit this process by any counter virtues it may possess, then, surely, improvement is to be hoped when patients seek this resort in the *early* stages of the disease. What do experience and observation teach? They tell us of almost invariable improvement and recovery at this time. Altitude contributes largely to this end. It is on these elevated plains and mountain slopes that a rarefied atmosphere and a diminished atmospheric pressure effect important changes in the breathing capacity of the lungs, which expand especially at the apices. This removes the susceptibility to apical consolidation and impairment and effects a

change sought to be attained by proper gymnastics, when altitude is unavailable. Add to this effect of altitude the benefit of a dry soil and a sunny climate, which will admit of out-door life during nearly the whole year, and a combination of circumstances exists highly favorable to the arrest of phthisis in its early stages. Usually these conditions lead to a vigorous appetite, a desire for increased exercise, and ultimately to permanent recovery.

When hemorrhages or local congestions are imminent in this stage, then great care is needed as to the elevation sought. Too much altitude will lead to undue expansion of the lungs and increase these susceptibilities. Hence judgment is required in sending patients into the regions in question. This cannot be too strongly enforced. Some patients need an elevation of only two thousand feet, while others will do well at five thousand or six thousand. Any attending heart lesion must be duly regarded, as a damaged heart is often taxed in its functions as the elevation increases. It is best always in cases of phthisis complicated with heart disease, to proceed cautiously into elevated districts, directing the patient to low or medium altitudes at first. He may be able to ascend as improvement follows.

Before leaving this subject of altitude, it may be well to quote some observations and conclusions from Dr. Williams's treatise heretofore cited, relative to the effects of rarefied air and elevation upon phthisical patients. These are thus summarized in different parts of the work: "Hypertrophy, or more development of the healthy lung tissue, shown by the physical signs and increased respiratory power.

"In consequence of the above changes, there is expansion of the thorax, which increases in circumference at various levels from one to three inches, such increase being independent of any augmentation of fat or muscle, as it takes place in patients who are losing weight, and occasionally in bed-ridden ones.

"The above thoracic expansion is always accompanied by diminution in the number of respirations, which become deeper, and by a slowing of the pulse.

"Absorption of atmospheric oxygen by the blood takes place more readily, while at the same time the carbonic acid formed within the body passes outward through the pulmonary tissue into the air, which is breathed with a greater degree of facility than at lower altitudes (Marcet)."

These observations are not by one observer only, nor are they confined to any special mountain region. They are summations from the best authorities and confirm the general tone of this paper.

Lastly, the aseptic quality of the atmosphere in much of the region designated is another important factor in the treatment of consumption by climate. It has been stated that in the stage of softening and extrusion of tubercular masses from the lungs the accompanying fever is due largely to blood poisoning. But sepsis is set up only in the presence of germs that float in the surrounding air. Where these germs do not exist, septic processes should be absent. This is, indeed, the case in the Rocky Mountain districts, as many observations show. There are many localities in which meats will not putrefy for many days even during midsummer, and when they do undergo changes, they are those of mummification rather than of putrefaction. Wounds rarely take on an unhealthy condition. During the year, the writer treated a number of gun-shot injuries, without meeting with a single instance in which there were any signs of sepsis whatever. Often persons far removed from a physician, in filthy camps or in other extremely unhygienic surroundings, will go days and weeks with severe injuries to the tissues, without developing blood poisoning. This insusceptibility to putrid and septic changes must be due to the aseptic quality of the air. And what direct bearing has this fact upon the consumptive? Evidently in such an atmosphere he should be in little danger of hectic fever in the later stages of his disease. And this is a confirmed fact. It is true the physician may be misled with cases sent here in a very late stage, as in these, as a rule, when there are cavities and solidified areas, softening sets in so rapidly and tissue changes go on so extensively that there is complete overwhelming of the system. While touching upon this point, it cannot be made too emphatic that it is very injudicious for consumptives to resort to most mountain climates late in the progress of the disease, as the final catastrophe is generally precipitated.

Whether bacteria are absent from the air in these regions, or only exist under conditions inimical to their development and activity, are questions which as yet, so far as the writer's knowledge goes, have not been decided. Bacilli are found in the sputa of consumptives here as elsewhere. Where many phthisical patients have long resorted, as in some of the older and larger

cities, an honest expression of the profession would no doubt favor the idea that the *climate has lost its virtues*. This may be due to impregnation of the soil, houses, and the atmosphere with germs, or to the fact that the comforts and confinement of city life are unfavorable to the disease. Much of the Rocky Mountain region being new or almost uninhabitated, new health resorts with accommodations for invalids continually springing into existence, the physician is left to exercise his judgment and preference where to send his patient.

During the writer's residence here he has met and had under treatment a large number of phthisical patients who had already tried the Pacific coast for relief. The change from the moist atmosphere to this dry climate was almost invariably attended with great relief to the attending catarrhal and bronchial disease, which in these subjects is quite noticeable and common. Even retirement from the coast to elevated districts failed in a number of cases to relieve the sufferer to the same extent he improved here. Hence it may be inferred that the slight humidity incident to many sections of this country can be always made available in the treatment of phthisis. A dry soil is usually associated with a dry atmosphere. By many authorities the former is held to be just as important as the latter.

The chief disadvantage to patients resorting to these elevated districts is that, after a period of residence, however great their improvement, they incur great risk of new and extensive outbreaks of the disease, in case they return to places nearly on the sea-level, or to a climate having a damp cold winter. The proper way to get the chief and lasting benefit of this climate is permanently to reside in it, if improvement follow one's advent. This fact has come to be pretty generally appreciated, and not a small percentage of the yearly immigration to Colorado, at least, is due to it.

The most common-sense deductions to be drawn from what has been said so far are these:

1. There is something to be gained by the climatic treatment of pulmonary consumption.

2. The time to begin it is at the first outbreak or manifestation of the disease. In those families in which the disease is hereditary, resort to this region should be made even earlier.

3. After the disease has made considerable inroad upon the system and medical measures have been exhausted, do not then advise the patient to seek a new climate with the hope of speedy improvement and ultimate recovery.

4. Physicians should always consider well the prognosis of the phthisis, when it is complicated with intercurrent trouble. A bad valvular lesion might of itself make the forecast of the disease unfavorable. So also certain organic affections of the liver and kidneys. It is not an unusual experience to meet with patients sent here for the benefit of their lungs, whom some intercurrent disease is sure to carry off.

In this shape we dismiss the present subject, hoping that what has been said will contribute something to the better selection of patients to be sent hither, and to the comprehension of the treatment of a disease which makes such fearful ravages upon the human family.

REMOVAL OF TWO-THIRDS OF A RIB.

BY J. A. MINICH, M.D.,
WORTHINGTON, IND.

John Hixon came to me in June, 1888, to consult me in regard to a tumor on his left side, which I found to contain pus. I lanced the abscess and it discharged about eight or ten ounces. This gave him some relief, but he returned again complaining of his side. I found crepitation in the rib at about its middle portion some distance from where I had lanced it, and with the probe I discovered the bone was diseased, but how extensively I did not know. He grew gradually worse and finally a troublesome cough also set in, and he could get no sleep or rest, and he became very much emaciated. I finally decided to remove as much of the rib as was diseased, which I did on January 7, 1889. I removed all of the sixth rib on the left side except about four inches next to the spine. It was so much diseased that it broke very easily in several places on removing. At one place beneath the rib there was about a teaspoonful of thick cheesy substance imbedded; this seemed to have no connection with the opening which had been discharging all summer and fall. Fortunately there was no opening through into the cavity of the pleura, and I succeeded in removing the rib without injury to the membrane.

The patient told me he had the best night's rest that night he had had for a year. And now, January 26, his cough has left him, the wound has healed, and he is free from all pain and is happy.

THE CONJUGAL STATE.

BY J. B. JOHNSON, M.D.,
WASHINGTON, D. C.

The experience of the world has long since declared that the union of one man and one woman in the association known as marriage, is the best possible relation for the sexes to assume or maintain in order to attain the most happiness, as well as the greatest degree of welfare and comfort, that the natural relations of the sexes demand. That such does not always lead to success, and prove a blessing, by bringing as a reward, happiness, prosperity and congeniality, is a fact beyond contradiction; and the question, why it does not always lead to the fruition of the object of its institution, is answered by the fact, that the preliminary courtship which leads to it, is not conducted with the same caution, judgment and frankness, which are brought to bear upon other important transactions of life. Courtship, instead of being conducted in a frank, honest and sincere manner, is marked by a system of concealment, disingenuousness and deception which endeavors to hide the multitude of faults that marriage generally discloses.

Those who associate with each other for the purpose of marriage, should be sincere, and endeavor to ascertain each others likes and dislikes, habits, mode of life, thoughts and sentiments; for it is important for each of the parties to it to learn the opinions of the other upon every subject in common between them, in order to insure harmonious action when brought into such intimate relations as exist between man and wife. It is the studied concealment of the true character of each from the other, during courtship, that gives rise to injury to the marital state. After marriage, those traits of character which were so studiously concealed before the nuptial relations were established, are recklessly and unreservedly manifested; and thus often results in a want of congeniality and harmony of feeling, thoughts and sentiment. The husband does not find the recent sweetheart in the new wife, nor does the wife find her lover in the husband; and often before a month has passed, the want of congeniality, and their unfitness for a life-time association with each other, is brought home to them in a most unhappy and disastrous manner.

If, after marriage, a want of harmony exists between man and wife, patience must take the place of affection, and forbearance with each other's faults becomes a duty; then discrimination and tact will make life not only bearable, but pleasant, and other ties may be formed which will bind the husband and wife in a firm, strong bond, such as they would at one time have deemed impracticable. Should husband or wife, or both, not possess this capacity, or disposition to make the most of an unpropitious marriage, a worse condition of affairs is usually excited. The husband becomes cold and careless in his attentions, while the wife grows indifferent, and shuns, rather than invites, his caresses. This growing indifference toward each other soon degenerates into estrangement, and as soon as this occurs, there often arises in the hearts of the self-deceived husband and wife a feeling of absolute disgust toward the other; and they find, alas! when it is too late, that there exists neither love nor congeniality between them. When this condition is fully realized by both, the disappointed husband, or it may be, the disappointed wife, sometimes looks abroad for that kindness and love which he or she expected from the other; and then the door is open for the temptation to conjugal infidelity. If the case goes on to extremities the husband seeks his affinity in another woman, while the wife gives her ear and smiles to some man who is polite and kind to her; and these associations soon produce a total and permanent disruption and abandonment of all their marital ties. Their marriage bed has no attractions for either, and each becomes cold toward the other.

The negligence of the beau and sweetheart in failing to ascertain before marriage the habits and sentiments of each other, preparatory to the establishment of matrimonial relations, is the cause, not only of many unhappy marriages, but also of many divorces. A husband who loves his wife, will make any sacrifice for her, and the wife who loves her husband is willing to risk her life in the duty of trying to please him. Like a true woman, every effort of her mind and body is dedicated to his pleasure and welfare; and every act she performs toward him is but the offering of an unselfish love; and when she feels the product of conception, the offspring of a holy marriage-bed, fluttering within her womb, her love toward her husband grows stronger, and no wicked thought of destroying it ever enters her mind. Under the influence of such love, the pains and suffering of maternity, and the duty of taking care of the babe of her bosom become a pleasure. A wife who does not feel this is a selfish woman, and is

true neither to herself, to her husband, nor to her offspring. Her selfish conduct may drive her husband to sexual depravity, and force him to those necessities of evil which vice always imposes upon the transgressor. Every effort a married woman makes to prevent conception is sinful, and in direct violation of God's command: "*Be fruitful and multiply*," and a conscientious physician cannot afford to compromise his manhood by lending his professional advice to an interruption of a normal operation of the laws of nature, in order to gratify immoral motives, or the caprice or the temporary inconvenience of the effects of procreation.

STRANGE EFFECT OF NERVOUS SHOCK.

BY J. C. MILNER, M.D.,
COMANCHE, TEXAS.

Allow me through your valuable journal to report the following case:

J. W., five years old, was burned when six months old on the right side of his face, the burn destroying the orbicularis palpebrarum. Cicatricial eversion of upper and lower lids followed, exposing the eye ball and a large area of epithelial tissue. The sight of the eye up to the time I now speak of remained good.

Some time in November last, the child, with his mother, was on a visit in the country, and in playing became fastened under the floor of an out-building. When discovered by his mother he was so impacted that it was necessary to dig him out. The mother reports the observance of nothing unusual except that the child cried, and finally sobbed himself to sleep. On the following day the child refused food. He did not appear to be sick, but had lost his usual energy and refused food altogether. The next day the mother, fearing he would be sick, returned home with him. Under the expectation of going home, he was induced to eat a small piece of bread, with sugar upon it.

About ten days after the fright, I was called in to see the boy. The father said that "Jimie had lost ten pounds in the last ten days." I found the patient greatly emaciated, without fever, refusing to lie in bed, his bowels and kidneys acting, but he rejecting food totally, having eaten not as much as one ounce since his fright.

I diagnosticated the case to be one of inanition, caused by nervous shock. I could not bring the electric current to bear; hence it was not used. The line of management consisted in sponge baths with warm water, in which were put soda and mustard, with nerve tonics, peptonized food, fruit, etc.—all of which had to be forced upon him. This continued for ten or twelve days, during which time I was satisfied the system was consuming by absorption and thus producing a state of blood poison, which I expected to end in death. The first indication of blood poison (if my theory be correct) manifested itself ten days after I first saw the case, and twenty-one or twenty-two after the fright, in a nervous rigor, lasting about one hour, followed by rise in temperature to 103° or 104° and loss of muscular power, with mental disturbance and prostration upon the bed. This condition was met with antipyretics and antiseptics. The patient now resisted swallowing everything offered either in the shape of liquids, food, or medicine. A wretched and aggravating cough now set up. We met that as best we could with a flannel jacket saturated with mutton tallow over which was sprinkled powdered capsicum mixed with sulphate of quinine, and adjusted closely to the surface of the chest. Cod liver oil was freely rubbed on the remaining part of the body. For three more weeks the little fellow continued in this condition, refusing all manner of food and drink except as it was forced upon him. When food was swallowed, it was only to undergo fermentation in the stomach, and to be passed off with the odor of sulphuretted hydrogen. During this time a corneal ulcer formed in the eye which had been burned, completely destroying the sight. Abscesses formed also over different parts of the body.

After about five weeks from the time of the fright, though every day for the last two of the five I expected death to end the scene, the system again rallied and small teaspoonful doses of some kind of nourishment could be taken. No medicine was given except a few drops of a hypnotic as required, to procure sleep; but gradually the desire for food returned, and the powers of digestion were restored, until now, eight weeks after the child received the fright, he is beginning to walk a little over the floor, holding on to articles of furniture. Am I correct in my diagnosis? Was I correct in assuming a blood poison by absorption? If so, how was the system sustained, and what were the eliminating forces that freed the system from the poison? A correct solution would be appreciated.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, January 23, 1889.

The President, W. W. Keen, M.D., in the chair.

Dr. Mordecai Price read a paper on

Amputations of Thigh and Leg.[1]

Dr. L. K. Baldwin, in opening the discussion, said: I have been much interested in the remarks of Dr. Price, partly because a gentleman called at my office this afternoon and asked me to look at an abrasion on the stump of an amputated limb. The amputation had been performed at the junction of the middle and lower third. It was just such a stump as I thought that he ought not to have had. The operation was performed ten or twelve years ago, and although he has worn a number of legs, the stump is always getting rubbed. The remarks of Dr. Price in regard to amputations near the joint are very good. There is no one more capable of speaking upon this subject than Dr. Price himself, for there is nothing like practical experience. His remarks are worthy of all consideration, and it would be well if they were followed out.

Dr. James Collins: I have listened with a great deal of earnestness to the remarks of Dr. Price on this question. He comes rich in that experience of suffering that makes men wise. I therefore attach great weight to his words. I could, however, but think that while the doctor is entirely right in his opinions, he may have forgotten the lectures given at the time he graduated. I have heard the professor of surgery say, and have seen him demonstrate, that the point of election for amputation of the leg was three fingers' space below the tubercle of the tibia. I think it well to mention this, and while I admit the great advances which have been made in surgery, yet, I think, that we should not cut entirely loose from all that has been done in the past. With reference to what has been said in regard to long stumps, I think that the surgeons of twenty years ago were deluded by the promises of the artificial-limb makers. The artificial-limb makers made demonstrations before classes in surgery, and led the surgeons to believe that if they had a certain form of stump they could apply the limbs better. They described their wonderful limbs that could almost walk without a man attached to them, and thus to a certain extent deceived the surgeon.

Dr. O. H. Allis: I would ask Dr. Price if in a case of injury to the foot, he would take off the limb say at the tarso-metatarsal joint, or go to the point of election below the knee?

Dr. M. Price: I should prefer to operate at the point of election. I think that even in an injury which would require amputation of the great toe, the patient would be more comfortable and walk better if the limb were taken off below the knee, although I do not say that I should do it.

Dr. H. R. Wharton: I agree very thoroughly with Dr. Price as to the necessity of securing a good stump, and as to the point of election in amputations through the leg. I have for some time made it a rule not to make any amputation near the ankle-joint, preferring to go some distance above, if I have to go above the ankle.

I, however, disagree with him in regard to the discomfort which a patient suffers with a Syme or a Pirogoff amputation. I have seen such patients get along very well, and walk with comfort. I also disagree with Dr. Price in regard to knee-joint amputations. I, of course, refer to amputation through the joint, the condyles being saved and the patella being left. I have seen these patients apparently walk with comfort and have a good stump. Where the amputation is one at the knee-joint, a portion of the condyles being sawed off and the patella removed, a square stump is secured which can be well covered. I have seen a number of cases of this operation, and in these the patients had good stumps.

I think that the main element of a good stump is a movable covering, the skin being perfectly movable over the bone. If the skin is bound down and is subjected to pressure, the patient will suffer from constant irritation, and will be apt to exhibit some of the forms of mechanical ulceration seen in stumps.

I agree in regard to the uselessness of trying to save too much time in amputations.

Dr. John B. Deaver: In the large number of amputations I do in the hospitals of Philadelphia, I never do a Syme, but I do a Pirogoff and a Chopart. We often have to be governed by the wishes of the patient. I have had cases where I advised an amputation of the leg in order to render the use of an artificial limb easier, but where

[1] See Reporter, Feb. 2, p. 135.

the patient has insisted that as much as possible of the limb should be saved. A Pirogoff does well. It answers better for a working man than for one under better circumstances. Osteoplastic resection of the foot gives the patient an almost useless limb. Yet it is a very nice and a very difficult operation. It has been performed only twice in this city, once by Dr. Hopkins, and once by Dr. F. H. Gross, at the German Hospital. The patient of Dr. Gross is still in the hospital. He is able to get around, but I do not think that he will be able to do hard work.

In amputations through the knee-joint I think that it is important to leave the patella, which serves partly to carry out the theory of Dr. Price of leaving a plane surface. When the patella is removed there are left two irregularities caused by the condyles. We must here be careful not to divide the ligamentum patellæ. If that is divided the action of the quadriceps causes retraction of the patella. I have, however, seen retraction in cases where attention was paid to this point. In such cases it would be better to do the amputation at the knee. This, of course, opens up the medulla, and exposes the patient to the dangers of septicæmia, but with antiseptic surgery I think that the risk would not be increased.

Dr. J. Price: Attention has been called to the locomotion of persons wearing artificial limbs. Dr. Price has not said very much about his own locomotion. He is very fond of using the gun, and I have often hunted with him from morning until evening, and can speak of the tolerance of a good stump and a good artificial limb. In his own case he has wonderful tolerance for prolonged walking and climbing.

I have watched many cases of amputation where the operation was performed years ago. One case, operated on by Dr. John Mitchell, I see sometimes with one crutch and sometimes with a crutch and a cane. In none of these cases is the locomotion good. The amputations were made at the points criticized this evening.

Dr. A. Hewson, Jr.: The only point which I have to offer is in regard to Pirogoff amputations. It has been suggested that no artificial appliance could be employed in these cases that would look well. In several of these operations, done by my father, I have seen a shoe so well applied to the stump that it was almost impossible to tell that the man had an artificial foot. The difficulty was overcome by a large spring being put in the place occupied by the ball of the foot, *i. e.*, extending from the heel toward the toe, so that when the heel was put to the ground there was not that sagging in of the shoe as occurs when simply a filled shoe is worn.

Dr. O. H. Allis: My own feeling is that where amputation is very low down near the ankle-joint, the limb is used almost as a crutch, whereas if the amputation is a little below the knee, the instrument maker can make so good an ankle-joint that the wearer can walk on any declivity almost as well as with the natural limb. When you try to piece out an ankle, the part cannot be used as a foot, but is more like a crutch.

Dr. Frank Woodbury: I should like to say a word in regard to a class of cases to which reference has not yet been made, that is, to amputation for disease, and particularly tuberculous disease of the joints. I would refer to a series of observations made by Ogille, in which it is stated that the prognosis of tuberculosis of the lungs is improved by an amputation, and that the larger the portion of the body removed, the better chance there is for the entire recovery of the patient. It seems that in certain cases of phthisis the nutritive powers are not sufficient to maintain the nutrition of the entire body, so if we can remove say one-eighth, or a larger portion of the body, the digestive function and the blood-making function are more than sufficient for the remainder of the body, and the nutrition is therefore improved.

This is directly to the point of operating in cases of joint tuberculosis, and also in the direction of the paper, that we should not endeavor to save all the tissue that is available.

Dr. M. Price: I agree with the statement of Dr. Allis that such appliances are just like crutches. A man with a well-made foot can readily go up stairs giving a little spring with the sound foot. I was able to play base-ball, foot-ball, and the like, and was at school for a long time before it was known that I had an artificial limb to any one with the exception of my room-mate.

In regard to Dr. Collins's statement as to the teaching when I was a student, Dr. Smith, who was at that time professor of surgery, was one of the most conservative of men. His statement was that we have to consider what we are doing in amputating, and consider the influence upon the man himself. As many of these patients are led into bad habits of dissipation by being invited to drink by every one they meet, it might, in these cases, be better to amputate

around the throat. I am not surprised that Dr. Collins has called attention to the fact that Dr. Smith amputated three finger's breadth below the tubercle of the tibia. Dr. Smith had been in the war, and had seen much to show him the usefulness of a proper-length stump.

If I were going to amputate near the knee, I would operate below the joint, giving the patient a knee-bearing leg, with the patella and all its attachments in place. As soon as you amputate the leg, retraction takes place. It is one of the secrets of treating a man with amputation to keep the stump straight. If the limb is left lying loosely on a pillow, there will be retraction of the muscles. Now and then I have to wear a peg, and it is then two or three days before I can straighten the leg. I would not suggest an amputation that opens the knee-joint. Where the operation suggested cannot be done, I would amputate at the junction of the lower and middle third of the thigh, and thus the knee-joint could be brought in the proper position.

In the case of workingmen who have passed that period in life when there is no chance of advancement, I have no objection to a Chopart, or any other amputation that will give the man a limb that he can walk upon. I am speaking of amputations that will give the man the same appearance that he originally had. I think we err in discussing the question of what ought or ought not to be done with the patient. We are there as his adviser, and it is our business to do the best for the patient. I say to him, such and such should be done. If he says that he will not have it, I decline to treat him.

—Dr. John Marshall, whose address is Chemical Laboratory of the Medical Department of the University of Pennsylvania, is engaged in examining the matters vomited or obtained by lavage in cases of supposed cancer of the stomach, and also of the blood in cases of sarcoma and carcinoma. Any physicians who have such cases, are requested to send the specimens of the vomit and of the blood (the last especially from an operation) to Dr. Marshall, at the above address, as soon as possible after obtaining them. A small quantity of ordinary ether should be added to the specimens before sending them to Dr. Marshall, so as to prevent decomposition. A statement of the nature of the case, and the results of any microscopical examination, together with the name and address, should accompany the specimen.

Reports of Clinics.

PHILADELPHIA HOSPITAL, JAN. 23.

CLINIC UPON DISEASES OF CHILDREN AND OBSTETRICS—DR. PARVIN.

Facial Paralysis of the New-Born.

I present to you an infant delivered six days ago. You observe that one side of the face is paralyzed, this paralysis manifesting itself if the child cries or sucks. An injury was done the right facial nerve by the blade of the forceps upon that side on which the palsy is now found, for in consequence of narrowing of the pelvic outlet—the pelvis was kyphotic—it was necessary to end the labor instrumentally. This accident is by no means a rare one following the use of the forceps. Yet it may occur, but very seldom, though the delivery is spontaneous. Still more, there may be the same paralysis in consequence of an intra-cranial lesion, but when this exists other parts are paralyzed also, and not merely the external parts; thus you will then find, for example, that the loss of power involves the veil of the palate.

In the variety of what is called obstetric paralysis here presented, the prognosis is favorable, while in that just referred to, it is the opposite. Almost all cases, scarcely an exception is ever seen, of facial paralysis from the forceps, recover, and usually within a few days. Therefore there is no indication for any treatment. But if by exception the paralysis should continue for a month or six weeks, the use of electricity would be indicated.

Cephalohæmatoma.

I showed you a week since this child suffering with a hæmatoma situated upon the right parietal bone, and then called your attention to the means by which you distinguished such a tumor from the caput succedaneum, or sero-sanguineous effusion occupying the presenting part of the child, which is so common a condition observed in the new-born that it may almost be regarded as physiological. But this is a rarer condition, occurring not oftener probably than once in 200 cases. Let me direct your attention to the bony margin lifted up, and so distinctly felt around the base of the tumor: this is one of the distinguishing marks of a cephalohæmatoma. It is possible such a tumor might for a moment be

confounded with a cerebral hernia; but such hernia would increase when the child cries, it might be partially reduced, pressure on it would cause nervous accidents, and possibly the opening in the skull through which the hernia escaped could be felt.

The rule is that such a tumor disappears in a few weeks whether anything or nothing is done, and therefore no active treatment is indicated. Very rarely suppuration occurs, and then of course the abscess must be opened, proper antiseptic precautions being used.

Jaundice in the New-Born.

I present you three infants with jaundice, that which is sometimes called physiological jaundice to distinguish it from a graver form usually associated with septic infection. This generally manifests itself three or four days after birth, and spontaneously disappears in a week or ten days. The most important points in the care of an infant affected by physiological jaundice are to see that the child has its daily bath, and that regular evacuations from the bowels are secured, calcined magnesia, for example, being given, if any medicine is necessary.

Changes in the Areola and in the Nipple caused by Pregnancy. Care of the Nipples in Pregnant Women.

You are all familiar with the fact that important, and in some cases distinctly characteristic, changes occur in the areola surrounding the nipple as a consequence of pregnancy, such as the swollen or puffed condition of this part, its becoming notably darker, and the greatly increased size of the glands opening upon its surface, glands which notwithstanding the differing statements of observers are most probably miniature mammary glands, and are commonly known by the name of Montgomery, a distinguished Dublin obstetrician many years dead, who very carefully observed and described the changes in them consequent upon pregnancy: my belief, however, is that they were first called after Morgagni. Now, one of the women before you is in the 8th month of pregnancy, and you see there is not the slightest darkening of the areola, and no enlargement of the glands opening upon its surface. You usually get no information in regard to pregnancy worth having if you examine the mammary areola in a blonde, or in a woman with red hair, or, finding it so free from changes, may hastily conclude that pregnancy is improbable, and thus be led astray.

The other women are presented that you may see in one the normal form and size of the nipple, and in the other a small and retracted nipple. And this leads me to say a word in regard to the care of the nipples in pregnancy, especially important if the woman be a primigravida. It is all-important if the mother is to suckle her child, that the nipple shall have a suitable form and size; a bad nipple may foretell fissures, abrasions, and ulceration, and consequent mammary inflammation and abscess. Now I believe very much may be done to educate, or educe a retracted nipple. Teach the woman by the use of the index finger and thumb to draw out the nipple, spending a few minutes two or three times a day in this process of education, for education it is in the etymological sense of the word. Let the woman too, wear a nipple shield of firm material that will not only prevent compression of the organ, but also secure for it ample room to grow outward. This treatment ought to be begun at least two months before the end of pregnancy.

Several years ago I lost faith in the prophylaxis of "sore nipples" commonly employed then, and commonly employed to-day, that is, by the application to them of alcoholic and astringent preparations. Nature meant the skin of the nipple to be pliable, and she also has protected it from the injurious effects of the fluids, contact with which it is normally subjected to, by an almost infinite number of fat glands. But the treatment mentioned hardens the skin, dissolves away the protective glandular secretion, and lessens the activity of the glands. Therefore I believe it to be utterly irrational, and I have seen no satisfactory results from its employment. It is wiser, I think, to keep the nipples clean by the occasional use of a little warm water, possibly soap sometimes employed with the water, and then only apply a little cocoa butter to them at night. Of course this treatment is not required until the latter part of pregnancy.

CLINIC ON NERVOUS DISEASES—DR. F. X. DERCUM.

Gentlemen: I shall bring before you to-day a number of cases of spinal disease, not so much because they are interesting in themselves as because they illustrate, in addition to gross disease of the spinal column, focal disease of the cord. It is by the study

of just such cases that we can best prepare ourselves for recognizing focal lesions of the cord, when no evidence of the same is afforded by an examination of the spinal column.

Pott's Disease.

Let us take, for instance, the case of the woman before us. It is a simple case of Pott's disease. The body of the first lumbar vertebra and to a lesser extent the bodies of its immediate neighbors are badly necrosed, so much so, indeed, that the spinal column has, as you see, a sharp bend in this region. The angle formed is so small that it is impossible for the patient to lie upon the back, but she is forced to rest upon either side. You can readily see what must happen to the contents of the spinal canal at the point of flexion. The calibre of the spinal canal is so much diminished that the cord is compressed, and we have very much the same set of symptoms as those derived from a transverse section of the cord in an animal or in a man whose spinal cord has been compressed by a tumor, or which has been cut across, it may be, by a bullet. Of course, there are certain differences, but they are matters of detail, and do not affect the general principles.

In the first place, we have, as you see, a paralysis of motion below the point of disease. I ask her to move her legs, and you see that she is powerless to do so. I next prick her limbs with a pin, and you observe that she gives no sign of pain. Repeating the test in various ways, you observe that she has lost all power of recognizing either touch or pain in the legs. Thus far we have established paralysis both of motion and sensation. In addition, we have, in this case, the added symptom of pain near the site of the disease. This pain is described by her as sharp and shooting, and radiates in a belt-like manner around her body. It is intense in character, and for a time was so severe that the patient was kept more or less under the influence of morphia. We must look for an explanation of its presence in the extreme distortion of the bodies of the vertebræ and the consequent compression of the nerves as they make their exit through the intervertebral foramina. Regarding the question of pain in focal diseases of the cord generally, for instance in tumors, I may say in passing that it may be absent or but slightly pronounced in growths having their origin in the substance of the cord, and is especially marked where the lesion involves the membranes or the posterior nerve-roots. It is almost invariably a prominent symptom and radiates along nerve-trunks having their origin at or below the level of the lesion.

In studying our patient more closely, we become aware that the paralysis of sensation and motion does not begin at the level of the flexion of the spinal column, but some distance below it. This is to be explained by the oblique and descending course of the nerves in this region. Take, for instance, the ilio-hypogastric nerve. You will remember that it takes its origin from the first lumbar nerve, its fibres therefore gaining an exit from the spinal canal between the first and second lumbar vertebræ. You will remember further that it is ultimately distributed to the skin of the hypogastric region and the buttocks. In testing our patient carefully, we find that as we proceed downward from the region of the diseased vertebræ, the patient continues to recognize the touch of the finger or the pin-point until the buttocks are reached. Here her responses become uncertain, and finally cease altogether.

You see at once then that to make a successful diagnosis of the level of a given lesion you must be thoroughly familiar with the origin and course of the various nerve trunks, while you should also bear in mind that the point of spinal exit of a nerve by no means corresponds to its level of origin in the cord. In fact the latter is usually much above the former, the difference in level being more pronounced as we go from above downward. In the present instance, the actual level of origin of the first lumbar nerve, of which the ilio-inguinal is a branch, is just beneath the lamellæ of the *eleventh dorsal* vertebra ; so that a lesion in the cord causing paralysis of this nerve would have to be sought for at this level instead of at the first lumbar vertebra.

Our patient presents in addition other symptoms which I prefer merely to mention, my object being rather to indicate general principles. You observe that her legs are in a condition of spastic contraction, and further that the muscles are much atrophied. These conditions are the result of degenerative changes in the segment end nerves below the seat of compression, as I may have further opportunity to point out. Both sphincters are also, as you would naturally expect in so complete a lesion of the cord, paralyzed.

But one more point of interest remains, to which I shall call attention. If you will observe her very closely while I again test her for sensation you will notice that the

latter is not as absolutely lost as is motion; and this is probably to be explained by the fact that the spinal cord, being compressed from in front, the motor tracts suffer *first* and suffer *most* while the posterior tracts are compressed later and less effectually. The posterior tracts indeed suffer in such a case by transmitted pressure from in *front*. The surgical indication in such a case would therefore be—extension having been tried and proving useless—to remove the lamellæ and spines of the diseased vertebræ. In the patient before us, however, the pronounced character of the disease and the extensive secondary changes that have ensued would discountenance any such procedure.

Crossed Spinal Paralysis.

In the next case we have before us a middle aged man who, while in a condition of good health, was struck on the shoulders by a heavy bale of rags, the bale falling from the height of a third floor. The man was walking at the time. The blow caused him to sit down forcibly on the pavement while his thorax was forcibly flexed upon his abdomen. Strange to say, after recovering from a momentary shock, he got up and walked home, and for a number of months thereafter attended to his occupation, that of carpenter. It was not indeed until seven months after the accident that he began to have difficulty in walking. His condition at present is extremely interesting. On asking him to move his legs as he sits in his rolling chair you observe that he moves his left leg quite readily while the right fails utterly to respond to the will. Testing him now for sensation you notice at once that he responds instantly when the paralyzed leg is touched and fails to recognize any impression on the leg in which motion is still preserved. In other words we have paralysis of motion on one side with paralysis of sensation upon the opposite side. We have here then exactly the same condition as we would find in an animal in which a hemi-section of the cord had been made. A tumor compressing one-half the cord would of course produce a similar set of symptoms. The seat of the growth would then be determined by the level of the anæsthesia plus the point of origin in the cord of the nerve fibres supplying the area above and below this level. Pains radiating around and down one side would probably, as in the present case, be an additional symptom.

It is hardly necessary to relate to you the explanation of crossed spinal paralysis. You remember, doubtless, that the motor fibres decussate in the anterior pyramids of the medulla, while the sensory fibres decussate along the entire length of the cord. Let us see how they were interfered with in the present case. On carefully examining the patient we find that the spines of the twelfth dorsal and first lumbar vertebræ are markedly deflected to the right, and it therefore appears that the bodies of these vertebræ underwent gradual softening after the accident, and that a *lateral* displacement finally resulted.

If I have succeeded merely in impressing you with the general method of examination for localized diseases of the cord, and in that term I include also the membranes, my object has been accomplished. One very important group of symptoms, however, I have not even touched upon, as a full discussion is not permitted by the time at our command. I refer of course to the tendon phenomena and reflexes. However, the following rule with regard to them holds good: You all know that if the cord of an animal be cut, just as soon as the shock of the operation passes away, the tendon phenomena, *e. g.*, the knee jerks, are increased. This of course also holds good in man. A division of the lateral tract by a bullet or by a tumor results in an increased knee jerk—*i. e.*, other things equal. Long continuance of the lesion may result in the contracture and wasting and so, as in the case of the woman you saw, the reflexes may be abolished. You should also remember, that if the lesion be lower down in the cord, *e. g.*, in the lumbar portion and termination, the end of the cord being destroyed the paralysis in the legs cannot be accompanied by reflex action, as there are no centres below the seat of lesion.

SURGICAL CLINIC—DR. M'CLELLAN.

Case of Dog-Bite.

Gentlemen: The first patient whom I shall show you this morning is a woman who received a few days since a very ugly bite from a dog, the injury involving the ala of the nose and the lower lip. There was no reason in this case to suppose that the animal was rabid: but I have known very troublesome results from similar injuries which were much less severe than those in the present case. It is well always to cleanse thoroughly a wound of this nature when it is first seen, and then to cauterize it. Punctured wounds are bad things to deal

with, owing to there always being a probability of inflammatory products being imprisoned; and when they occur from the teeth of animals they should, when it is feasible, be carefully sucked out before a caustic is applied. It is well also to administer a cathartic, to put the patient on light diet, and, when it is applicable, the wound should be treated antiseptically. In this case, as you see, such a course has been well rewarded.

Two Cases of Punctured Wound of the Scalp.

Here are several cases of punctured wounds of the scalp, from an examination of which you may gain some practical hints. The first was inflicted by a stick falling on the man's head; caries of the frontal bone resulted, and subsequently the dura mater became involved, and the operation of trephining had to be done to relieve distressing symptoms. The other man fell a week ago, striking his head against some sharp object. The wound healed quickly, but there is evidently fluctuation beneath the scalp tissues. I think, as a general rule, punctured wounds of the scalp should be converted into incised wounds, so that they may be cleansed of all foreign matter and washed out.

In both of these cases the damage done involved the entire scalp, and owing to the loose connection of the latter to the pericranium, if inflammation occurs and results in suppuration, pus will often burrow away from the site of the injury to some dependent position.

Case of Felon.

The next patient has had a felon. This is a most painful affection. It is not always easy to determine the cause, but most frequently felons occur from bruises in persons whose vocation subjects the fingers to much use in hot or cold water. There is very apt to be more or less injury to the deeper parts, and if the periosteum becomes involved the bone is often destroyed. The great pain is due to the blood-pressure on the nerves at the ends of the fingers. It is less severe if only the soft parts are concerned, as the swelling then becomes diffused; but when the trouble is with the tendon or periosteum the theca confines the pus to a very limited area, and the peculiar, intolerable, throbbing pain occurs. The treatment of felon consists in preventing suppuration, or if that is unavoidable, in hastening it. If it is tried early, the inflammation may often be aborted by painting the finger with strong iodine liniment, or with nitrate of silver, followed by strapping. This will cause a few moments' suffering, which will speedily diminish and disappear. If, however, suppuration has begun it should be encouraged by hot dressings, and when fully established the felon should be freely incised in the middle line over the tendon down to the bone. If you apply poultices, do so warily, and for a few hours, for they are a remedy almost as bad as the disease, if improperly used. I am sure I have seen numbers of fingers lost through over-poulticing by ignorant persons. From their excessive use the soft parts become macerated and boggy, and the pus finds easy inducement to travel toward the hand. After incision, a soothing mild dressing may be used, and, if you prefer it, one which is antiseptic.

General Lipomata.

Here is a man about forty years old, who is afflicted with a number of growths upon his back, neck, throat, arm, groin, and thigh, which upon examination feel doughy and lobulated. They are insensible to pressure and are evidently fatty tumors, or lipomata. They occur generally in parts exposed to friction and pressure, but it is rare to meet with a patient presenting so many of these tumors at the same time.

Epithelioma.

Here are two cases of epithelial cancer. The one on the lower lip has possibly been caused by smoking a clay pipe. Its removal before greater involvement of tissue occurs would certainly lessen suffering, and perhaps not be followed by a return of the growth. The other case, in which the epithelioma is on the anterior part of the neck, involves many great blood vessels and nerves on both sides, and is not amenable to operation. Fortunately the man is not now suffering.

—The number of cases of infectious diseases in New York City shows some diminution over that of a few weeks ago. For the two weeks ending Feb. 12, the following statement is furnished by the Sanitary Bureau of the Health Department: Typhoid fever, 14 cases and 2 deaths; scarlet fever, 666 cases and 96 deaths; cerebro-spinal meningitis, 5 cases and 2 deaths; measles, 595 cases and 40 deaths; diphtheria, 388 cases and 103 deaths; small-pox, no new cases, one death.

PERISCOPE.

Recurrent Pneumothorax.

Dr. Samuel West, Assistant-Physician to St. Bartholomew's Hospital, refers to a most important and interesting case, published by Mr. Gabb, in which there had occurred three attacks of pneumothorax, with complete recovery. He says he had a similar case under his care at the beginning of this year at the Chest Hospital, Victoria Park. The history of the case is as follows:

W. H. D., 22 years old, was admitted on January 3, 1888, into the Chest Hospital, Victoria Park, complaining of shortness of breath. The attack came on, he stated, without any apparent cause, on the morning of December 23, on getting out of bed. The breathing was so short that he found it necessary to remain at home, though he did not lie in bed; and, as after some days it still continued short, he applied for admission into the hospital. He had not felt ill or suffered in any way except with the shortness of breath.

The patient was a healthy-looking young man, slightly built, but well-developed and muscular. There was no dyspnœa evident. The shape and movements of the chest were symmetrical, but the percussion note was tympanitic over the whole right side from the apex to the base, back and front. The tympanitic resonance extended to the left edge of the sternum right down to the xyphoid cartilage, and the liver dulness did not rise above the seventh rib. The heart was displaced to the left, the apex beating under the left nipple. The vocal vibrations could be feebly felt and heard over the whole side, but the respiratory murmur was absent except at the base behind, where weak and distant amphoric breathing was audible. There was no bell sound or succussion. The lower edge of the liver could not be made out. The opposite lung was completely healthy, and the other organs seemed normal. The case was clearly one of pneumothorax without effusion, and in the process of resolution.

The subsequent history of the case is simple. The shortness of breath quickly disappeared. The patient looked and felt well, and gained flesh. The abnormal physical signs gradually vanished, and on February 6 the following note was taken: "The shape of the chest is symmetrical, the movements free, but, on deep inspiration, there seems to be a little more expansion on the left side, especially in the axilla. The liver dulness begins at the sixth rib in the nipple line. The cardiac dulness is of its normal size, and the apex in the proper place. The percussion note is still a little more resonant on the right side; the breath sounds are distinctly audible and vesicular in character over the whole side down to the base. In the mid-axillary region a little fine crepitation is heard, probably pleuritic, for it is in this place that the patient has complained of pain for the last few days."

The patient's previous history was good. He had had no serious illness except scarlet fever and measles, but he had been regarded as a rather delicate child, having been subject to a cough on catching cold ever since an attack of bronchitis at the age of 3 years, but he lost his cough as he grew older. His father was living and well, but his mother died after a confinement. He had a brother and a sister, both strong; and he considered himself strong and active, and enjoyed athletic exercises.

Now comes the interesting part of his history. Last August, while walking quietly, he was suddenly seized with pain above the right clavicle, and felt a bubbling sensation in the right side. The breath at the same time became very short, and he had a rather violent cough—as he called it a "churchyard cough"—which he had not suffered from before the breath became short. He was able to keep at his work, however, but had to avoid all hurry and exertion for about a fortnight, when he appeared to get quite well. In the beginning of November, the morning after a game of football in which he was several times charged violently, he became again short of breath. The breathing continued short for about a month, but at the end of that time he found himself quite well again, and continued well until the present attack three weeks later. The two previous attacks were, he stated, all similar to the present one.

In the absence of direct evidence, there is a very strong probability that the previous attacks were, like the present, due to pneumothorax. The last attack was without doubt pneumothorax, but he came under observation rather by accident than of necessity, for it was not until he had had the dyspnœa for ten days that he presented himself at the hospital, and even then the dyspnœa was so slight that he grumbled at being kept in bed.

There are two facts about pneumothorax,

Dr. West remarks, which, though well established, are not generally known: that it is of not uncommon occurrence in the apparently healthy; and that it may develop in the latent insidious way it did in this case, and without the violent symptoms which frequently accompany it. The interest of this case and of that published by Mr. Gabb does not lie in their illustrating these points, but in the fact, which they establish, that a patient may have more than one attack of pneumothorax and recover completely. Dr. West says he does not see any reason why this should not be so, but he does not recollect any recorded case of the kind, so that Mr. Gabb's case is a very important contribution to the literature of the subject.—*British Med. Journal*, Jan. 12, 1889.

Biology of the Pancreas.

Dr. Polïkarp D. Küvshinsky, of St. Petersburg, has published recently (*St. Petersburg Inaugural Dissertation*, 1888, pp. 56) a valuable contribution to the biology of the pancreas, based on a number of laborious and careful experiments on dogs with a permanent pancreatic fistula. The scientific chapter in question attracting as yet relatively little attention, the following short summary may be placed before the readers of the REPORTER. 1. The pancreatic secretion never ceases altogether, not even in sleeping or fasting animals. 2. It manifests, however, considerable variations in regard to its hourly and daily amount, as well as to its physical and chemical properties; and that not only in individual animals, but even in one and the same dog examined on various days, all other conditions being equal. 3 Given a healthy dog under normal conditions, some of the variations prove to be distinctly determined by taking food; some by mental, some by physical, state. 4. As to the influence of food, a daily course of the secretion is, generally speaking, this: As a rule, shortly after the meal the secretion increases until it reaches its primary maximum during the second half-hour, less frequently during the first half-hour; after a more or less short interval, it decreases fairly markedly to rise and sink slightly again and again, the secondary maxima being reached at about four-hour intervals after the meal. 5. An average daily quantity of the juice in a non-fasting animal, weighing about nineteen kilogrammes, amounts to 335 cubic centimetres (eleven fluid ounces). 6. The proportion of solid constituents in a normal pancreatic juice varies between 1.6 and 7.7 per cent., gradually rising to its highest point about seven hours after taking food. 7. The "secretory pressure" in a dog's pancreas amounts to 280 milligrammes of an aqueous column, or to 21.4 of a mercurial one. In a rabbit's gland it is equal to from 219 to 225 (Heidenhain). It is probable that in man, too, the pancreatic tension is nearly as low. Since a catarrhal condition of the duodenum in dogs and rabbits seriously interferes with the escape of the juice into the bowel, we may safely assume that duodenal catarrh in human beings must similarly give rise to a more or less complete cessation of the juice's flow. 8. The secretion is most distinctly influenced by psychical agents. In a dog, kept fasting for twenty-four hours and then excited by having food placed before it, a considerable increase in the secretion takes place, fairly rapidly. The juice secreted contains a relatively low proportion of solids (3.5 per cent.), but still possesses a normally energetic digestive action. 9. Hence, we are justified in assuming that in man, too, appetite plays an important part as a stimulant for the secretion and, consequently, as a powerful promoter of digestion and assimilation. 10. During sleep the secretion gradually sinks to a fairly low level, the fall going on synchronously with deepening sleep; while on awakening the secretion gradually increases. 11. Alcohol in a diluted form and in moderate doses, is a powerful stimulant to the pancreas, since it rapidly causes a very considerable and fairly prolonged increase in the amount of the juice, which acts energetically. This increase lasts twenty-four hours. 12. Hence, the internal administration of spirits before and during meals can be actually beneficial in anæmic and weakened persons, convalescents, etc. 13. Morphine, however used—hypodermically or internally—is a powerful pancreatic depressor, since it in two minutes inhibits, and subsequently, in thirty to twenty minutes, completely arrests the secretion for from one to three hours, the effects being very pronounced even after small doses (*e. g.*, one-tenth of a grain to a dog of 21.5 kilogrammes in weight. The effect corresponds generally to the size of the dose. 14. Cocaine similarly manifests an inhibitory action on the pancreas, which, however, on the whole, is less powerful and by far less prolonged as compared with morphine.

Spasmodic Urethral Stricture from Anal Fissure.

In the *Med. Record*, Jan. 26, 1889, Dr. L. Bolton Bangs communicates an account of a case in which he believes a more or less permanent stricture of the urethra was due to reflex action of the spinal cord from an irritation at the anus.

The patient was forty-one years old, a painter by trade. Twenty years ago he had syphilis, followed by secondary symptoms, but for many years subsequently he had no evidence of it whatever. For several years he had been subject to attacks of painter's colic, and at such times the associated constipation was very obstinate. About six years ago he began to have indescribable sensations in the region of his bladder, and pain during urination, but he had never had any urethritis or disease of the urethra or bladder to which these sensations could be attributed. About two years ago he acquired a specific urethritis which lasted acutely some weeks; then became chronic, and finally terminated at the end of six months. About eighteen months ago he had an attack of painter's colic, accompanied with constipation, and then experienced intense pain in the rectum, which was most marked after defecation. This pain became constant, gradually increased to extreme intensity, and he suffered from it, both after and before a stool. With this pain in the rectum, he had a gradually increasing difficulty of urination, the urine passing in a small stream, and at times only in drops, accompanied with pain in the penis and in the pelvis generally.

At length the difficulty of expelling the urine became such that his physician was compelled to resort to the use of the catheter, in order to relieve the bladder of a certain amount of urine which was retained. For the two months preceding his coming under Dr. Bangs's observation his troubles, both as regards the pain in the rectum and the dysuria, increased so greatly that the use of the catheter was continuous, and the latter finally set up a mild form of urethritis, which aggravated his symptoms. The pain referred to the rectum and to the bladder became so severe that he was obliged to resort to hypodermic injections of morphia. When Dr. Bangs first saw him, the man was anæmic, weak, and in constant pain, unable to empty his bladder without the use of the catheter, and under the necessity of being constantly under the influence of morphia. He was unable to discriminate between the pain in his bladder and that in his rectum. He was tormented with frequent desire to urinate, and although he could expel some urine with great straining, the feeling that his bladder was not emptied was so intense that he could hardly be restrained from passing his catheter, which he always carried in his pocket for the purpose. His meatus urinarius admitted a 32 French *bougie à boule*. At four and three-fourths inches was a stricture of 26 French. A solid sound of the latter size (26 French), after being obstructed for a few seconds at the membranous urethra, slipped into the bladder. On withdrawing, it was strongly held by the urethra, which alternately relaxed and contracted upon the instrument until the latter was free in the penile portion. There was evidently a spasmodic condition of which there could be no doubt. It is true, Dr. Bangs remarks, that such a condition in the deep urethra might be due to a stricture of large calibre in the penile portion, and if it had been nearer to the meatus he would have paid more attention to it; but inasmuch as the patient complained so greatly of the pain in the rectum, he thought that perhaps the secret of the trouble might be found in or about the latter. On exposing the anus it was found to be violently contracted. The anal region was very sensitive and it was only with great difficulty that the patient could be induced to relax the sphincters sufficiently to enable Dr. Bangs to find that he had three bluish-red exceedingly painful fissures of the anus. This seemed a good opportunity to test the question of cause and effect by observing the result of treating the anus alone. Accordingly the patient was etherized, and the sphincter-muscles were paralyzed digitally. Nothing whatever was done to the urethra, and the catheter was taken away. This was on June 7. On the 9th it was recorded: "The patient passed urine and fæces spontaneously, and with much less pain, being but slight during urination and not nearly as great after defecation."

From this time on improvement was progressive. There was none of the spasmodic straining to empty the bladder, there was no retention of urine, and the urethritis gradually subsided. Ten days later, a sound as large as could be insinuated through the stricture at four and three-quarters inches, namely, 30 French, was easily passed into the bladder, without any resistance and without any spasmodic contraction about the instrument upon its withdrawal.

On June 26 the patient was discharged from the hospital cured. Dr. Bangs states

that for the past six months he has been intermittently under observation. He has been treated for "painter's colic," and has had none of the obstinate constipation, no pain in his rectum, and no trouble whatever with his urethra or bladder.

Intubation with an Ordinary Rubber Tube.

Dr. Geo. O. Williams says, in the *Med. Record*, Jan. 26, 1889, that quite a number of patients die of diphtheria in consequence of the obstruction to respiration caused by the closure of the fauces from tumefaction of the tonsils and uvula, the larynx at the same time being intact. The majority of those who die within the first forty-eight hours die in this way. He then refers to a case of this character. The disease had existed forty hours. The child was eleven years old. The fauces and soft palate were covered with exudation. The throat was closed. Respiration very labored. Constant restlessness had been present for thirty-six hours. All the indications of slow suffocation were present. The child was informed of what it was desired to accomplish, and his promise to assist as much as possible was secured.

A soft rubber tube was then passed beyond the obstruction, and its extremity left just at the larynx. The boy nodded his head to indicate that it gave him relief and was in proper position. Within three minutes he dropped into a motionless slumber of absolute rest. The distressing breathing was instantly relieved. The sleep continued an hour. At the end of that time a little mucus obstructed the tube, and he awoke and pulled the tube from its place. It was immediately replaced. The tube extended six inches from the mouth. An attendant constantly supported this extremity. An ink mark on it, on a line with the teeth, designated the proper distance for introduction. After a few hours the care of the tube was intrusted to the friends. It was maintained in use for seventy hours. It was removed for cleansing, and for nutrition and medication at proper intervals. At the end of that time the subsidence of the tumefaction permitted its discontinuance. The tube measured seven-eighths of an inch, outside measure. No complication occurred in the case and a good recovery followed. He says he does not recall any published account of such a procedure in diphtheritic cases, but thinks it likely, from its simplicity and efficiency, that it must have been in use by others.

Inoculation with Tuberculosis by way of the Skin.

Von Lesser states in the *Deutsche med. Wochenschrift*, No. 29, 1888, that a woman 48 years old, who had been previously always healthy, had frequently washed the clothing of her husband who died of general miliary tuberculosis. In this patient a tumor the size of a cherry was found on the lowermost part of the volar surface of the right arm. The tumor proved on extirpation to consist of an alveolar structure with giant cells and central caseation; ascending from it caseous infiltrated streaks of tissue could be traced upward on the skin. Microscopically the skin appeared unchanged; only in the deep layers around the bases of the sweat glands there was great infiltration of cells. On the eighth day after extirpation of the tumor a tuberculous paronychia developed on the left ring-finger, which healed after being scraped.

Von Lesser regards it as probable that in this case the tumor developed through penetration of the virus by way of the sweat glands. The skin was intact as far as could be discovered by microscopic examination, and for the virus to cling to it under such circumstances seems to the author to require, next to hereditary taint, long maceration of the skin in a fluid containing the tuberculous poison.—*Centralblatt f. d. med. Wissenschaften*, Dec. 15, 1888.

Naphthalin Rash.

In the Moscow bi-weekly *Meditzinskoïe Obozrenië*, No. 16, 1888, p. 316, Dr. S. Prëobrajensky communicates an interesting case which tends to upset the common opinion that naphthalin, when administered internally, produces no accessory symptoms, since it is not absorbed by the gastro-intestinal mucous membrane. A boy, 16 years old, suffering with obstinate diarrhœa, took sixty grains of the drug in the course of forty-eight hours. By the end of this time diarrhœa ceased, but the patient's whole body, except the face and neck, became covered with a slightly itching, profuse rash, in the shape of fairly regular, circular, slightly prominent, brown-red patches one-half centimetre in diameter. After other two ten-grain doses, the face and neck became similarly studded. When naphthalin was discontinued the rash gradually disappeared, to be followed about the fifth day by a free desquamation. The temperature remained normal throughout.

Slight Aortic Insufficiency.

Some instructive experiments on artificially induced aortic murmurs were published some months ago by Dr. Timofejew (*Berlin klin. Wochenschrift*, Nos. 24 and 25, 1888), in which he showed that a very slight aortic insufficiency may exist without producing a diastolic murmur, but that in such cases a distinct accentuation of the second sound can then be heard; he also found that with greater but still slight insufficiency, though a murmur is produced, this can be made to cease by diminution of the blood pressure, either by venesection or by section of the spinal cord. These experimental observations are in full accord with the well-known clinical fact that an aortic bruit is sometimes temporarily much less pronounced than usual, and may even occasionally disappear. An interesting paper has just been published by Professor Carl Dehio, of Dorpat (*St. Petersburg med. Wochenschrift*, No. 50, 1888), in which he gives the details of a case which illustrates this variability of some aortic bruits very well. The patient was a student who had suffered from syphilis. At times he experienced severe pain in the region of the heart, accompanied by dyspnœa, headache, giddiness, and faintness. He had consulted several physicians, some of whom had detected a murmur, while others had declared there was none. Professor Dehio found at first, while the patient was sitting, merely some accentuation of the second sound, but as soon as he stood up, a blowing murmur was audible over the whole of the body of the sternum synchronous with the second sound, and prolonged to the end of the diastole. After a time, this became less and less perceptible, and finally vanished, but, on the patient moving or working his arms about, it reappeared. Tracings taken with a Dudgeon's sphygmograph showed that while the patient was in a recumbent posture, there being no murmur, the pulse, which was beating 80 per minute, was of a normal but weak character, with a slight distension wave and a low blood pressure, the secondary waves being only just perceptible. On standing up, the beats increased to 88 per minute, the bruit becoming then audible, the tracing assumed the character frequently observed in cases of neurotic cardiac palpitation, the pulse wave being higher, but falling rapidly, and the secondary and tertiary waves being well marked. After considerable exertion, when the bruit was louder still, the beats being, however, only 76 per minute, the distension wave was three times as high as when the patient was lying down, and it fell very quickly, being in fact the typical *pulsus celer*. It is seen that the bruit was dependent on the initial blood pressure due to the force of the contraction of the left ventricle, rather than on the mean intra-arterial pressure, which was probably not increased, since, according to the researches of Riegel and of Wetzel, there is no increase in the mean pressure, where the secondary waves become more pronounced. It is evident from the tracings that whenever the primary wave increased, the secondary waves increased also; and thus that, while when the patient was in a recumbent posture, there was but a gentle backward stream through the defective valves, yet, upon a slight amount of exertion, the velocity of this stream was greatly increased, and thus became capable of producing a murmur. This difference between a gentle and a rapid stream can be easily illustrated by compressing an india-rubber tube through which water from a cistern is flowing, when the murmur, which can both be heard and felt, is readily found to depend on the velocity of the water. Dr. Dehio remarks that he cannot well have mistaken a murmur of hæmic origin for a slight aortic insufficiency in this case, for the whole history, the dilatation of the heart, the occasional whistling character of the murmur, and the serious subjective sensations of pain and palpitation all point to organic mischief. Again, the insufficiency must, he thinks, be of slight extent, as the dilatation of the left ventricle was but very moderate, and as Duroziez's double bruit was not audible in the femoral arteries. —*Lancet*, Jan. 19, 1889.

Case of Sebaceous Cyst of the Groin.

At a meeting of the Brooklyn Surgical Society, March 15, 1888, Dr. Rockwell presented a photograph of a case taken at the moment of operation, with the following history:

A woman had been brought to his office by a physician, who supposed her to be suffering from inguinal hernia, but was not quite satisfied with the diagnosis. On examination, a tumor, which had been slowly developing for two years, was found in the left inguinal fold, where it lay parallel to Poupart's ligament, which it directly covered. It was about nine inches long and two or three inches in diameter, looking like a large sausage. It had never been reducible, nor had it given any pain. Impulse on coughing and resonance on percussion were wanting. The finger could

readily be passed under the tumor and into the inguinal canal, outside of the tumor's wall. It was flat on percussion, and gave the impression of containing fluid or colloid material. A diagnosis of cyst was made, and, on opening the tumor at the time of operation, it was found to contain about half a pint of fluid rendered semi-solid by the presence of enormous quantities of cholesterin crystals, though little if any true sebaceous matter was found. It was probably a sebaceous cyst modified by location and pressure to its peculiar shape. The sac was dissected out, and the patient rapidly recovered. The case was of interest from a diagnostic point of view, as it might easily have been mistaken for one of femoral hernia pushing up over Poupart's ligament, or hydrocele of the round ligament, both of which it resembled in many of its clinical features. —*Brooklyn Medical Journal*, Jan., 1889.

Origin of Human Diphtheria from a Similar Disease in Birds.

At the time when Nicati published some statements tending to demonstrate the identity of the contagious element of diphtheria in children and in chickens, Mágnin, as the result of numerous observations and microscopical investigations, also published statements denying such identity. This was in 1879. Since that time, thanks to the development of bacteriology, Loeffler, and Cornil, and Babés have shown the almost complete identity of the bacilli found in the false membranes of children and birds. More recently this statement has been confirmed by the investigations of Menziés, Delthil, Pamard, Bouchard, and Leissier. Menziés has endeavored to show that diphtheria was caused by the dejections of birds, through the medium of water which has percolated through the deposits of dove-houses or poultry-yards into wells. In the epidemic, which was reported by the author, the atmosphere seems to have been the medium of propagation. He believed that the disease was carried to the island in which the epidemic occurred, and in which nothing of the kind had previously been known, by diseased turkeys. In the course of five months, 125 of a population of 4,000 were attacked with diphtheria, and 36 of them died. This island was in the northern part of the Greek Archipelago, Skiatoes by name, and the epidemic continued during five months of the year 1884. The diseased turkeys showed false membranes of a gray color upon the velum of the palate and upon the pharynx. In one of them, the process extended to the larynx; the membranes were not very closely adherent, and could be readily removed. The underlying mucous membrane bled but little, and the glands of the neck were not very much swollen. In one of those which recovered, there was paralysis of the feet, and the animal was unable to walk. The conclusions which were drawn from this epidemic are:

1. There is in turkeys a kind of diphtheria which resembles that which occurs in human beings in its symptoms, its evolutions, and its gravity.

2. Its virus may be transmitted by the atmosphere to man, communicating the disease to him, and then developing into an epidemic.—*Glasgow Medical Journal*, Jan., 1889.

Hereditary Chorea.

The Lyons correspondent of the *Bulletin Médical*, Jan. 6, 1889, says that G. Lenoir has devoted an interesting thesis to hereditary chorea. He concludes that there exists a special form of chorea deserving the name hereditary, and that it should be placed in the group of arhythmic choreas. It is a disease of adult life and of maturity. As regards etiology, only one essential and so to speak necessary influence is found, namely, heredity. In symptomatology it is characterized by an insidious appearance and by the slowly progressive march of the choreic symptoms, which, at first sight, do not differ from those of the common chorea of Sydenham. A more attentive examination, however, shows as an essential difference that the patient is able to stop the movements by an effort of the will. Disturbances of intelligence and of memory are very frequent. The diagnosis is easy enough. Convulsive tic is perhaps the only affection with which hereditary chorea may be confounded. A number of cases described under the names chorea of adults and of the old should in future be studied with more care with reference to heredity. It is very probable, indeed, that a large number of these cases should be classed as hereditary chorea. The progress of the disease is slowly progressive, and it ends in loss of mind and in death. While the prognosis is fatal for the disease it should be reserved for the children and the descendants up to the age of fifty years at least. But it is very interesting to note that hereditary chorea never skips a generation. If a child of a choreic escapes the disease his own children will be free. No treatment up to the present time has given satisfactory results.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE STATE BOARD OF MEDICAL EXAMINERS.

As the fate of the bill to establish a State Board of Medical Examiners in Pennsylvania has not yet been settled by the Legislature, we would add a few words to what has already been said in the REPORTER about it.

Just at present the opposition to the passage of this bill is being pushed with great vigor and, while nothing new is said against it, the old objections are brushed up and brought out in a way to mislead those who are not familiar with them and their history.

The opponents of the bill may, we believe, be divided into the following classes: First, and most influential, a large part of the homœopaths, who fear that a board containing—as it ought to—a majority of men of the "regular" school would have a prejudicial influence upon the maintenance of their separate existence. This opposition is natural; but we are happy to believe that the most intelligent and honest so-called homœopaths are not afraid to rely upon the justice and fairness of such a board as is proposed, and that they see the need for examining boards unconnected with medical schools as clearly as any medical men do.

Second, there are among the opponents of the bill certain men who pose as the most orthodox of the "regular" school, who go about talking of the "Code of Ethics" and trying to work up a scare about homœopathy, which is in ludicrous contrast to the fear of some of the homœopaths just spoken of. These men do not represent the mass of the regular profession, either in their abject fear of homœopathy or in their intemperate assaults upon the character of homœopaths in general.

A third class of opponents is found in the teachers and *attachés* of certain medical schools which make a pretense of maintaining a high standard of medical education, but whose graduates have hitherto found it harder to pass the examinations of State Boards than it was to get their diplomas. This kind of opposition is easy to understand, if its motive is known; and when its motive is known it will no doubt meet with the contempt which it deserves.

The last class of objectors to which we wish to allude is made up of those who are the open supporters of fraudulent and ignorant methods—or no-methods, as Carlyle would say—of treating the sick. This is a motley crew of vitapaths, electropaths, eclectics, Christian scientists, pow-wow doctors, and who can tell how many more. These are not very conspicuous in their opposition to a State Board of Medical

Examiners—although they are deeply concerned—because their cause is being maintained much better than they could maintain it, by the homœopaths who are afraid of the "regulars" and the "regulars" who are afraid of the homœopaths. We believe we voice the best and fairest professional sentiment in Pennsylvania, when we say that the most upright and intelligent members of the medical profession want what the general community wants, viz: that a license to practise in this State shall be given to those only who can pass an examination before a Board chosen by the State, and subject to the scrutiny of all of its citizens, and that the possession of a degree shall not carry with it the right to practise after a mere registration. We believe that all who oppose a law of this kind are consciously or unconsciously working to keep the practice of medicine open to the ignorant and unprincipled, and we trust that nothing will prevent the adoption by the Legislature of the Bill now before it.

TREATMENT OF LOCOMOTOR ATAXIA BY SUSPENSION.

In a recent lecture at the Salpêtrière, in Paris, Professor Charcot has called attention to a very interesting suggestion in regard to the treatment of locomotor ataxia, or tabes, which was first made by Motchoukowsky, of Odessa, in Russia, and which Charcot has adopted with very striking results. In introducing this method to his hearers, as reported in the *Gazette Hebdomadaire*, January 25, 1889, Charcot took pains to make it clear that he had used every care to avoid the error of being carried away by the fascinations of a new method, or of attributing to it what might more properly be credited to other factors in the case. He also stated that the cases in which he had treated it were actual cases of ataxia—a statement which is hardly needed from so eminent and experienced a clinician.

The method of Motchoukowsky is simply suspension, as usually practised when a plaster jacket is applied for disease or deformity of the spinal column. The discovery of the method was purely accidental. Motchoukowsky was treating a patient with tabes, who had also a scoliosis. To remedy the latter, he suspended his patient and applied a plaster-of-Paris jacket. In a very short time the patient found himself very much relieved of the fulgurating pains with which he had suffered; and careful testing assured Motchoukowsky that this relief was caused not by the jacket, as he at first supposed, but by the suspension. After this he used suspension upon a large number of ataxia patients, with marked advantage to almost all of them.

This interesting result has now been confirmed by Charcot, who, since last October, has treated fifteen patients by suspension, with remarkable success. The method has been used two or three times a week, for a minute or two for the first few times and for two or three minutes at the succeeding ones.

The relief experienced by the patients consists in a marked diminution of the characteristic pains of locomotor ataxia, and of the inco-ordination. One of the most striking results of the method of treatment is the restoration of the sexual functions; and an investigation disclosed the fact that suspension was actually employed in establishments which exist in Paris for the cure of impotence!

It will prove of value to those who take an interest in this subject if they can go over the details given by Charcot of the effect of suspension in four or five of his cases; but without this, our readers may well believe that a method endorsed by so famous a teacher must have something of actual value in it. Its extreme simplicity, the ease with which it can be carried out, and the results attributed to it entitle it to the serious consideration of all medical men. If—as is to be sincerely hoped—the experience of Motchoukowsky and of Charcot

are repeated in other lands than Russia and France, it will revolutionize the treatment of locomotor ataxia, and perhaps influence the treatment of other organic or functional diseases of the spinal cord.

If any of our readers have under their care patients with locomotor ataxia, we would be glad to have them apply this method and report its results for the benefit of their fellows, and as a contribution to medical science.

INFECTIOUS ULCERS OF THE CORNEA.

At the meeting of the Société d'Ophtalmologie of Paris, January 8, 1889, M. Abadie called attention to the conditions essential to the production of serious infectious ulcers of the cornea. These are: Erosion of the epithelium; inoculation with a pathogenetic microbe; and sufficiently prolonged contact of the organism and the denuded corneal tissue. The last condition might be considered to be included necessarily in the second; but M. Abadie points out that time is an important element, and that this accounts for the fact that serious ulcers of the cornea are perhaps never met with except in patients who are careless in their habits, and not strict in regard to cleanliness.

The treatment of these ulcers is indicated by their etiology. In the earliest stages they may be combated—and sometimes cured—with repeated washings with an antiseptic solution, and the insufflation of finely powdered iodoform. At a later period they require section, according to the method of Sæmisch, or cauterization with the galvanocautery, with opening of the anterior chamber. In some cases a cure cannot be effected without thorough disinfection of the nasal cavity; for which purpose M. Abadie has used, with excellent results, a solution of mercuric chloride, one part to two thousand of water.

This last suggestion, in regard to the treatment of grave ulcers of the cornea, is one which may well be borne in mind; for it is easy to carry out, and as rational as it has proved to be useful in M. Abadie's hands.

CLASSIFICATION OF ABSCESSES.

As a result of his interest in bacteriological studies, Prof. Verneuil has recently proposed to classify abscesses according as their pus contains only the micrococci constantly found in pus, or also other microbes not characteristic of pus. This is in our opinion a somewhat premature suggestion. It might be interesting and instructive to have a collection of carefully observed data in regard to the distribution of the various microbes according to the character of the abscesses in which they are found; but far too little is known now about the relation of microbes to pus formation to justify any attempt to classify abscesses in the way Verneuil suggests.

More than this, an attempt of this sort leaves out of sight the fact that the mere presence of an abscess or its peculiar character often signifies less from a practical standpoint than the state or condition of the patient or the situation of the abscess. These are at present the things to be regarded in estimating the significance of abscesses; although it would undoubtedly enlarge our knowledge if it could be shown that abscesses of certain sorts are caused or always accompanied by certain microbes, and that the absence of such microbes is evidence that pus is of a more—or less, as the case may be—malignant character. With some definite information of this sort, the treatment and prognosis of abscesses might perhaps be modified, and certainly would be more accurate than they are at present.

Unfortunately, however, there is nothing of this sort known now. The bacteriological theories in regard to the formation of pus are still in a very immature state, and by no means ready to pass from the laboratory to the clinic.

REMOVAL OF FOREIGN BODIES FROM THE NOSE.

In a letter to the *Lancet*, Nov. 3, 1888, Dr. Charles W. Dodd describes an ingenious method of removing certain foreign bodies from the nose, which is worthy of extensive notice. He introduces a tube into the free nostril and blows suddenly into it so as to cause a strong pressure of air, passing back of the septum, behind the foreign body. He recommends, if this does not succeed at once, that the opposite nostril be closed by the surgeon while he blows, and the closure suddenly removed when the pressure is strong enough.

For the carrying out of this method Dr. Dodd uses a soft rubber tube provided with a hard rubber end made to fit the nostril; but almost any tube could be made to do the work if the surgeon is possessed of a little dexterity.

TREATMENT OF TONSILLITIS.

The treatment of tonsillitis is unfortunately by no means established upon a firm and uniform basis; and, so long as this is the case, it is worth while to call attention to methods which are said to have proved useful at the hands of intelligent medical men. For this reason, it is interesting to note that Dr. A. Hillaby, in the *Therapeutische Monatshefte*, December, 1888, speaks very highly of the results obtained by administering at the outset a simple carthartic, such as the infusion of senna, and following this up with doses of nine or twelve grains of salicylate of soda, several times a day. Under this treatment, he says, the fever and the local inflammation subside rapidly; the activity of the skin is re-established and the formation of abscesses in the tonsils is prevented. He recommends diminishing the dose of salicylate of soda when the inflammatory process is subsiding, but to continue it in small quantities until a cure seems assured.

—Small-pox prevails among the Indians at Fort Buford, Dakota.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

DOSE AND PRICE LABELS OF ALL THE DRUGS AND PREPARATIONS OF THE UNITED STATES PHARMACOPŒIA OF 1880, ETC. BY C. L. LOCHMAN, Translator of the first and second editions of the German Pharmacopœia, etc. Third edition, revised and enlarged. 9 x 4¼ inches, pp. xvi, 201.

We have already noted with approval a former edition of this excellent book. It is primarily intended for the use of pharmacists; but is of such a character as to be very useful to medical men. It gives, in alphabetical order, the Latin and English names of all the drugs and compounds contained in the last U. S. Pharmacopœia, with a brief statement of their derivation, dose, and medical properties, with blanks for writing in the price of different quantities. It contains also an appendix, in which a number of common mixtures are described and a short account is given of many new drugs which have not yet been placed in the Pharmacopœia. A full index adds to the value of the book.

TEXT-BOOK OF MEDICAL JURISPRUDENCE AND TOXICOLOGY. BY JOHN J. REESE, M.D., Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania, etc. Second edition. Revised and enlarged. 8vo, pp. xvi, 646. Philadelphia: P. Blakiston, Son & Co., 1889. Price, $3.00.

Those who have had the pleasure of attending upon the lectures of Prof. Reese at the University will look upon the appearance of this second edition of his excellent manual as the return of an old friend. In it are found the same charms of a clear and graceful style, and the same merit of thorough and accurate teaching. The book covers the whole range of subjects coming under the general term medical jurisprudence and toxicology, and gives in admirable shape what physicians and lawyers ought to know about the medico-legal relations of deaths from suspected violence and poisoning, about feigned diseases, pregnancy, abortion, feticide, infanticide, legitimacy and inheritance, rape, insanity, medical malpractice and life insurance.

The author discusses all these subjects with due consideration of the medical and legal sides of each, and with a judgment and discrimination which are the result of years of practice as a teacher and as an expert witness in the Courts.

It is a pleasure to be able to speak in such unqualified terms of approval of any book; and we feel sure that those who turn to it on our recommendation will not be disappointed in it. It is a work which does great credit to its author, and its paper, printing and binding are equally creditable to its publishers.

LITERARY NOTES.

—*The North American Practitioner* is the name of a new medical magazine to be published monthly by Charles Truax and Company, Chicago. It will be edited by Drs. Bayard Holmes and Junius C. Hoag in the interests of the Post-Graduate Medical School of Chicago. The first number presents a good appearance and makes a favorable impression.

CORRESPONDENCE.

The Medical Examining Board.

TO THE EDITOR:

Sir: I see the fight on the Medical Examining Bill has begun, and the warring factions may think it senseless. It might be better for us to yield a point to the other fellows than to have the whole thing "dished." For instance, give them a show on "theory and practice," for an examination their own way. I am no lover of the homœopathic system; but we must recognize that there are just as true gentlemen, loyal citizens, and Christians practising in the other schools as in our own, and legally we are compelled to recognize them, if not professionally. So we may as well yield to the "legal," and be done with it. I have therefore suggested to Representative Randall to amend the "Walk bill" by making the number of the Board twelve, instead of nine: six to be chosen from the Regular, three from the Homœopathic, and three from the Eclectic school, to be chosen from the registered lists of practitioners of over ten years' practice, regardless of political faith. This is only simple justice; there are many excellent doctors who are not members of any medical society, and it is not right to debar these men from positions on that account. Cases of gross injustice in medical societies are not uncommon, nor is professional courtesy or ability confined to them alone. Besides this, in a work of this kind the support of every good practitioner and man is wanted, and no society should put itself as the arbiter of his fate or promotion. Also, that eight members be a quorum; this keeps the representation even. That the Secretary and President be not of the same school. That the examinations on anatomy, physiology, chemistry, toxicology, pathology, hygiene, surgery, and obstetrics be before the whole board (or quorum); that no applicant be obliged to state his or her school of practice, or exhibit any certificate or diploma until after this examination. On the branches of "Theory and Practice of Medicine" and "Materia Medica," the examination to be before the examiners of the Board belonging to the school to which the applicant belongs. That the exclusive use of Latin names in answering questions shall not be required; and that all practitioners of medicine now registered according to law have issued to them a license to practice, and all be obliged to post the same in their office.

On such a bill all fair-minded doctors could agree; the gentlemen of the different schools could surely repress their prejudices while examining on the branches that all concede to be essential and in which there is no difference of opinion.

The above is merely suggestive, but I hope it will be of some help to the brethren who are trying to improve the quality, if not the quantity, of the profession.

Yours truly,

Marienville, Pa., Feb. 7, 1889. S. S. TOWLER, M.D.

Removal of Gun-Powder From the Face.

TO THE EDITOR.

Sir: In the REPORTER, Feb. 2, p. 152, Dr. John Gray reports his method of removing gun-powder from the face. I cannot quite agree with him in his method, although he was successful. In allowing supuration to take place scarring is more likely to occur. This I always try to avoid, but it cannot always be done when the entire structure of the skin is burnt through. If only the outer layer is destroyed the supurating method can be used without much danger of destroying the deeper structures by subsequent inflammatory action. I will report a case which I saw with another physician, and give you my method of treatment.

W. J., about 21 years old, was standing over a blast in a slate quarry when it was discharged unexpectedly; his face was filled with powder, and so deeply that in many places the powder penetrated through the skin; his eyes were filled with powder, the cornea of one was deeply burnt, and powder lodged in its structures. The patient was almost insensible to any manipulations about the face. We removed every particle of powder or colored tissue from the face with scalpels, simply scraping the face clean; iced water was used to wash off the detached particles. This was a slow process, but it was a success. The same method was used to remove the powder and burnt tissues in the eyes, using finer instruments, however. Instead of washing the eyes with lint, they were freely syringed out with ice-cold water. The powder and burnt structures of the cornea were completely removed by the scraping and syringing. The only dressing used was lint, repeatedly changed to keep the face cool. The young man made a complete recovery. The cornea was restored entire. There was no scarring of the face,

nor did any specks of powder remain. The face was kept covered with moistened lint as long as the structures remained unhealed. There was no suppuration, and consequently no scars. After the necessary cold water dressings to the eyes, small powders of calomel were dropped into them two or three times a day; whether the latter were of benefit or not I cannot say.

Yours truly,

JOHN M. CURRIER, M.D.

Newport, Vermont,
Feb. 6, 1889.

A Plea for Skimmed Milk.

TO THE EDITOR.

Sir: I want to call your attention to one matter in the milk bill now before the legislature. I think it should be altered so as to permit of the sale of pure unadulterated and undiluted *skimmed* milk. The only way to encourage temperance amongst the laboring classes is to give them a substitute for alcohol, which they will otherwise drink. *Unless food is made cheap high license or prohibition will be valueless in saving the laboring class.* As medical men we all know that to the laborer a pint of *skimmed* milk, otherwise pure and undiluted, represents a value as a force-producer and muscle-maker which the addition of the ordinary percentage of cream by no means increases in equal ratio to the additional expense. For the one he will probably pay five cents a quart, for the other ten cents a quart. I am heartily in favor of the heaviest penalty for milk, and indeed all food adulteration and dilution, but I am much opposed to the restriction of the sale of pure unadulterated skimmed milk, which is nutritious, healthful and within the means of the poorest laborer. Let him have it and plenty of it, in fact, let all his food be cheap and pure—milk, meat, bread and water, and in that way there will be a marked difference in the health and sobriety of these classes.

Yours truly,

JOHN M. KEATING, M.D.

Philadelphia,
Feb. 9, 1889.

—The Philadelphia *Ledger*, Feb. 16, says that physicians in Lowell, Mass., have formed an association "to guard themselves from imposition by transient people who have been in the habit of evading payment, going from one physician to another after having exhausted their credit."

NOTES AND COMMENTS.

The Welfare of Pharmacy.

The *Pharmaceutical Era*, Feb., 1889, says: The welfare of pharmacy depends upon the emphatic maintenance of special skill as a condition of its practice. As a mere division of commerce, without special learning, it is evident that the business of pharmacy must go under. The man who is to supply medicines, duly apportioned not to prove poisons, cannot take all his risks and pay all his expenses if he undertakes to trade wholly upon the business plane of the grocer, the clothier, the hardware dealer. A few weeks ago, a country grocer sold what he supposed to be "salts." It was sulphate of zinc. The wife of the purchaser took three teaspoonfuls. He is a man of grim determination. The grocer has made a hurried inquiry into the differences between kinds of salts, but one thing he is now sure of, it will not pay him to deal in any kind of salts for medicine. It is true all the way up, it does not pay any man to deal in chemicals unless he knows what they are. If the pharmacist reaches out of his proper pursuit and deals in certain common wares to eke out the scantiness of cheapened reward, let him all the more hold fast to his anchor of special skill in his proper calling, unless indeed he is ready to give up altogether. The welfare of every pharmacist stands with his professional training, and the good of the body of pharmacists stands or falls with the general basis of learning in pharmacy.

Cocaine in Cancer of the Breast.

J. F. Somerville states in a letter to the *Lancet*, Jan. 26, 1889, that a patient was operated on about two years ago for cancer, the entire left breast being removed. Twelve months after the operation the disease reappeared and developed so considerably that the same surgeon was again consulted, and he pronounced the case hopeless. Three months later the usual intense pain which accompanies such cases set in, and it became simply a question of alleviating suffering. After the usual remedies for relieving pain had proved ineffectual, Mr. Somerville tried a cocaine ointment (one part in twenty). It had, he says, a marvelous effect; the pain was subdued almost immediately, and remained continually subdued by its use. He states that it was used for two months, there being no occasion during that time even to increase the strength. The patient died Dec. 24, without the least suffering.

Oil of Turpentine in Diphtheria.

In the *Omaha Clinic*, Jan. 1889, Dr. J. H. Peabody has a communication on the treatment of diphtheria with oil of turpentine. He refers to a former communication by him published in the REPORTER Sept. 9, 1876, at a time when the use of the oil of turpentine for this purpose was not mentioned in most if any of the current text-books.

Dr. Peabody says: "I have carefully selected from 613 cases of throat disease, occurring in my practice during the last fifteen years, 175 cases of diphtheria. I say carefully, for I do not wish you to think that any case of follicular tonsillitis has been included in the 175 cases. If any error has been made it is in placing some mild cases of diphtheria among my 438 cases of tonsillitis, as I treat them at the onset with exactly the same remedies used in diphtheria; and I am confident I have jugulated many a case of this fell disease and prevented its spread in schools and homes where I have used turpentine."

During the past four or five years he says he has employed the following:

℞ Ol. terebinthinæ . . . . . f℥ ii
Sacch. albi . . . . . ℥ ii
Pulv. acaciæ . . . . . ℥ ii
Aquæ . . . . . f℥ iv

Misce. Sig. Shake up and give a dessertspoonful every three hours to an adult or to a child twelve years old. Alternate with two grain doses of quinine given in coffee.

In sthenic cases in the adult he allows a dessertspoonful of liquor ammoniæ acetatis with five drops of the tincture of aconite root, every three hours until there is some abatement in fever. If the patient is not decidedly better by the second or third day, tincture of the chloride of iron is given in large doses, and the patient is sustained with brandy in proper doses. By this means, a child 12 years old gets about twelve drops of the oil of turpentine every three hours. He also has a vapor diffused through the room by pouring turpentine and water on a hot brick, or by a water-bath. Strangury has in several instances occurred to a slight extent in his practice with the dose mentioned.

He says he has been called in consultation in a number of cases after violent septic poisoning has occurred, and has derived no benefit from turpentine in the heroic dose of a teaspoonful. Tincture of iron and chinoline with brandy in large doses are then indicated; but under any and all treatment the mortality is fearful.

A Characteristic Reaction of Bismuth.

A solution of iodide of bismuth in iodide of potassium is sometimes used, under the name of iodobismuthate of potash, for the research of the alkaloids. It gives insoluble, orange-yellow compounds with many natural inorganic bases, but gives no indication of the nature of the alkaloid found. I have thought, writes M. E. Léger, in the *Journal de Phar. et de Chim.*, Dec. 15, 1888, that this would be otherwise should we use such a reagent in finding bismuth. I used a reagent composed of cinchonine, 1 part; iodide of potassium, 2 parts; distilled water, 100 parts. The cinchonine is dissolved in water with the aid of a few drops of nitric acid; the liquid is heated and the iodide added. This solution, added to one of nitrate of bismuth, gives an orange-yellow precipitate. It should be used in excess, avoiding solutions containing hydrochloric or sulphuric acid; it must not contain too much nitric acid. This reagent may be used for metals precipitable by sulphuretted hydrogen, whose sulphides are insoluble in sulphhydrate of ammonium. It gives, with minimum solutions of mercury, a greenish-yellow precipitate, turning black with excess; maximum solutions give yellowish-white; cadmium, white or yellowish; silver, the iodide if the argentic salt is in excess, yellow if the reagent is in excess; copper (minimum), precipitate of cupric iodide; maximum, brown maroon, containing iodine, copper, and cinchonine; lead, sulphur-yellow precipitate, soluble in an excess of nitrate of lead, and containing iodine, lead, and cinchonine.—*Amer. Jour. Pharmacy*, Feb., 1889.

Lanolin in Suppositories.

According to M. L. Broutin, *Bull. Com.*, Nov., 1888, lanolin greatly facilitates the introduction into suppositories of extracts or other substances soluble in water. He thinks that when the choice of an excipient is left to the pharmacist, the latter may properly replace a small quantity of the cacao butter with lanolin. The following formula is cited as having given excellent results: Dry extract of hamamelis, gr. xii; lanolin, gr. cxl; cacao butter, ℥ vii; for 25 suppositories. The extract is heated with a sufficient quantity of water, to which the melted butter is added by degrees. The mass should be run off as soon as it commences to thicken. The suppositories are entirely homogeneous.—*Amer. Jour. Pharmacy*, Feb., 1889.

Incubation of Scarlet Fever.

At the meeting of the Nottingham Medico-Chirurgical Society, Jan. 4, 1889, Dr. Whitelegge read a paper on the duration of the incubation period in scarlet fever. Dealing first with experimental evidence, he took exception to Trousseau's view that inoculation is the only means of determining the latent period of a disease, pointing out that the period is not always constant even in inoculated diseases, and that the latency of an inoculated disease is usually shorter than that of the same disease when acquired without inoculation. The latent period of inoculated small-pox, for example, cannot be accepted as even approximately true of ordinary small-pox. A similar consideration applies to cases of infection by milk, and to surgical scarlet fever. For practical purposes, reliance has to be placed mainly on the result of observation of individual cases, and the evidence of this kind is divisible into four classes: (1), cases following a single exposure; (2), cases in which a maximum limit can be fixed; (3), cases in which a minimum limit can be fixed; and (4), indirect evidence derived from massed observations of a certain kind. The first and third are open to error, since infection may be carried for a time before infecting the system; the value of the second and third is mainly confirmatory or corrective. The estimate given by earlier authorities is much too long. In many instances the range adopted is so wide as to be useless for guidance in practice, and it becomes necessary to ask if there is not some well-marked usual period which would hold true of the great majority of cases. Murchison and Squire have shown that the usual latency is short, not exceeding three or four days at most.

Many cases were cited in support of this view, including fifteen which had come under Dr. Whitelegge's own observation; and stress was laid upon the constancy of the three days' incubation in the cases of definite limited exposure in infected ambulances recorded by Dr. Tonge Smith and others. Among the confirmatory indirect evidence, he said, is the comparative rarity of appearance of rash on Wednesdays, possibly accounted for by exceptional conditions on Sunday; and also the sudden reduction in the average number of second attacks in infected households about three days after the average date of cessation of acute symptoms in the respective first cases, followed by an increase about three or four days after the average date of commencement of desquamation in the first cases. It has been found that, of the new cases occurring in a house after removal of a patient to hospital, three-quarters presented a rash within five days of the removal. Instances of protracted incubation are to be regarded with suspicion, partly for the reasons already stated, but also on account of the difficulty or impossibility of excluding more recent sources of infection. The majority of ordinary cases are infected from unknown sources, and, if they happened to be exposed to known infection a week or two previously, they might rank as examples of prolonged latency. After reviewing the evidence, Dr. Whitelegge expressed the opinion that the usual period of incubation is three days, or, at all events, between two and four days; and that it is rarely less than one day, and very rarely, if ever, more than seven days.—*British Med. Journal*, Jan. 26, 1889.

Case of Acute Cirrhosis of the Liver.

Körner communicates an account of this case to the *Deutsches Archiv für klin. Medicin*, xlii, S. 615. A woman 20 years old was received into the hospital after she had been sick some days with headache, lassitude, nausea, and, more frequently, vomiting. On her admission the patient had no fever, the thoracic viscera were healthy, the liver and spleen not enlarged, the uterine adnexa free. The belly was a little swollen, and somewhat tender on pressure in the neighborhood of the pylorus and cæcum. The breath was fetid. The urine contained no albumin. The bowels were moved first on the day following admission, after the administration of castor oil.

In a few days there was slight rise of temperature in the evening and slight jaundice. On the fourth day after admission the lower border of the liver was felt in the mamillary line one centimetre (.39 inch) below the edge of the ribs; the liver itself was very tender. The patient was very restless. Two days later jaundice was very marked. The liver now projected five centimetres (about two inches) below the ribs, and extended into the left hypochondrium. The urine contained much bile pigment, and was only secreted in small quantities. There were hemorrhages from the nose and gums. Some days later there was a subsidence of the swelling of the liver. Numerous crystals of leucin and tyrosin were present in the urine. On the tenth day after her admission the patient died with

symptoms of acute œdema of the lung. At the autopsy numerous hemorrhages were found in the skin, and in the mucous and serous membranes. The liver was nearly normal in size, ochre-yellow in color, its capsule opaque in places and thickened. A microscopic examination of the tissue demonstrated the disease to be an acute cirrhosis of the liver.—*Centralblatt f. d. med. Wissenschaften*, Jan. 5, 1889.

Nikiforow's Carmine.

Dr. Nikiforow (*Zeitschrift für Wiss. mik.*) recommends a formula for a carmine stain which acts intensely on the nucleus, and can be used with advantage for staining specimens in toto, and which does not require after treatment with the strong acids which act harmfully on the tissues. It is prepared as follows: Take three parts of carmine, 5 parts of borax and 100 parts of water, and boil in a porcelain dish until a small portion of the carmine has dissolved. Add sufficient ammonia to dissolve the remaining carmine, and the liquid takes on a deep cherry-red color. The mixture is now evaporated by boiling to somewhat more than one-half its volume. Carefully neutralize with dilute acetic acid, when the cherry-red color gives place to one of a carmine tint. The secret is not to get too much acid (Grenacher's carmine), for such a preparation will require after treatment with an acid (? alkali). The safest way is to add the acid slowly and experiment from time to time. When the solution is prepared, a few drops of carbolic acid may be added, and it will keep indefinitely. Tissues which have been preserved in alcohol are stained by it in about fifteen minutes, though no overstaining takes place after twenty-four hours.—*Microscope*, Jan., 1889.

A Beautiful and Durable Cement for Ringing Balsam Mounts.

Mr. J. D. Beck sends the following to the *Microscope*, Jan., 1889: To a thick solution of gum arabic add a little glycerine to prevent cracking. Ring balsam mounts with this first, then finish with the same cement colored with magenta, or fuchsine, or the "Diamond" black dye dissolved in water. Ornament with gold paint, etc., and finish with "Winsor & Newton's" mastic picture varnish. Try cement on a blank slide; if brittle when hard, add a little more glycerine, so that it will harden in twenty-four hours without brittleness.

Surgical Treatment of Chronic Cervical Adenitis.

The Lyons correspondent of the *Bulletin Médical*, Jan. 23, 1889, says that M. Poncet has made a communication to the Academy of Medicine on the surgical treatment of chronic adenitis. He distinguishes two kinds. In the first the glands are superficial, although sub-aponeurotic, and extirpation can often be accomplished with the knife or the scissors. In the second the deep carotid or subclavian glands are affected, and the difficulties of extirpation are increased.

Surgical intervention may be divided into several steps. In the first the glands are exposed by incising the skin and soft parts. The incisions should be long, even measuring at times fifteen centimetres (nearly six inches). The second step comprises the extirpation or the destruction of the diseased glands. The use of the knife is simple and easy for superficial glands, but becomes dangerous in deep glands on account of the risk of wounding the vessels and nerves. The diseased gland must first be fixed with the left index finger and then punctured with the point of the knife. Through this opening a small curette is introduced and part of the diseased tissue removed; a larger curette is then inserted and the sub-capsular enucleation of the gland completed in a few seconds. The same operation is repeated for each gland, and in this way as many as ten or fifteen may be removed at one sitting.

The third step consists in covering the whole wound with a layer of iodoform, inserting a drainage tube through the whole length of the wound, letting it just come out of the inferior angle, and in taking a number of stitches to insure immediate union.

He states that recovery is very rapid, occurring in from fifteen to twenty days, and that it is permanent, several patients having been seen completely cured two years after operation.

Combination of Syphilis and Cancer.

Lang states in the *Wiener med. Blätter*, No. 10, 1888, that he had previously observed three cases in which cancer had arisen from syphilitic ulcers; in one case the ulcer was upon the face (rodent ulcer), in another under the tongue, and in the third upon the lower lip. He then presented a fourth case in which a carcinoma had developed upon the anterior edge of a syphilitic ulcer of the palate. The diagnosis was established by microscopic examination in all cases.—*Centralblatt für Chirurgie*, Dec. 15, 1888.

Benefits of Vaccination.

In Paris, where the law requiring vaccination is feebly enforced, the mortality from small-pox ranges from 136 to 10.1 to the 100,000 inhabitants, while in the principal German cities, where the vaccination laws are rigidly enforced, the death-rate is but 1.44 to the 100,000 inhabitants. London, under compulsory vaccination, has a death-rate from small-pox of but .6 to the 100,000 inhabitants. On the other hand, in the Canton of Zurich, in Switzerland, since the compulsory vaccination law was repealed in 1883, the death-rate from small-pox has risen steadily from 8 to 85 to the 100,000 inhabitants.

A report lately published by Mr. Ritchie, President of the British Local Government Board, with reference to the recent epidemic of small-pox in Sheffield, shows that of the children under ten years of age, 95,000 were vaccinated and 5000 were not. Among the vaccinated there were 189 cases of small-pox with 2 deaths; among the unvaccinated there were 172 cases and 70 deaths. Keeping these proportions, if all the children in Sheffield had been vaccinated, there would have been 200 cases of small-pox among them and a fraction more than 2 deaths; if none of the children had been vaccinated, there would have been 3337 cases and 1330 deaths, 600 times the mortality with universal vaccination.—*Sanitarian*, Jan., 1889.

Alcoholic Solution of Hæmatoxylin.

Dr. G. Cucatti (*Centralblatt für Bakteriologie und Parasitenk.*) gives the following formula for making a hæmatoxylin solution which possesses the advantages of never turning bad and of staining only the chromatic part of the nuclei, the color being fixed most deeply in the karyokinetic figures.

Dissolve 25 grm. (6½ drachms) of pure potassium iodide in 25 ccm. (6¾ fluid drachms) of distilled water, and pour the mixture into a glass-stoppered bottle containing 75 ccm. (2⅓ fluid ounces) absolute alcohol, shaking the whole repeatedly. Then grind together in a mortar 75 c.grm. (12½ grains) of hæmatoxylin crystals and 6 grm. (1½ drachms) of alum. When these are intimately mixed, add 3 ccm. (50 minims) of the iodide solution. Keeping the mixture well stirred, add little by little the rest of the solution, and then pour into a well-stoppered bottle, and leave for ten to fifteen days. At the end of this period, shake up well again and in an hour or two afterward filter, and preserve the filtrate very carefully to prevent evaporation and deposit of iodide crystals. This solution only stains up to a certain point, consequently the sections may be left in it almost indefinitely.—*Microscope*, Jan., 1889.

Toxic Effect of Cocaine.

Dr. Moizard reports in the *Journal de Médecine*, Dec., 1888, that a child 4 years old took by accident four grains of cocaine. There was no immediate effect; the child went quietly to sleep. One hour afterward he awoke in frightful agony. The face was pale, the respiration difficult; there were nausea, pains in the upper portion of the chest, formication, cramps of the limbs, and great muscular agitation. The child could get no rest, and was a prey to terrifying hallucinations. An enema containing eight grains of chloral, followed two hours later by one containing five grains, was given. The child began to get quiet. During the night it slept, but was frequently awakened by convulsive movements. On the following day it was perfectly well.—*Amer. Jour. Pharmacy*, Feb., 1889.

Relative Age in Procreation.

At a recent meeting of the Hungarian Academy of Sciences, Prof. Korösi read a paper on the influence of parents' ages on the vitality of children. The point is one which has hitherto received but scant attention at the hands of ethnological statisticians, but M. Korösi has collectd some 30,000 data, from which he deduces the following conclusions: Mothers under the age of twenty, and fathers under twenty-four, procreate children endowed with a less aggregate vitality than the offspring of parents of maturer ages. These children are especially liable to lung diseases. The healthiest children are those whose fathers are from 25 to 40 years of age, and whose mothers are between 20 and 30. He affirms that the best results are obtained from the union of a man the senior of the wife, but a woman between 30 and 35 will fare best with a somewhat younger husband. The wife of a man between 30 and 40 should not exceed 30 years of age, and whenever the mother's age exceeds that of the father by more than five years the health and vitality of the offspring are likely to suffer.—*Medical Press and Circular*, Jan. 23, 1889.

The Nature of Milk.

The results of a study of this subject were lately submitted by M. A. Béchamp to the Paris Society of Pharmacy. The author's conclusions are (*Union Phar.*, Dec., 1888): Milk is not an emulsion. The milky globules are not simply fat globules, but true adipose vesicles in a freed condition. Cow's milk contains, beside casein, albuminoid substances which are not free, being dissolved in combination with alkalis. Human milk is not, strictly speaking, a casein milk; it contains a ferment which is peculiar to it. (See *Comptes rendus*, xcvi, p. 1508). Milk coagulates spontaneously, *i.e.*, without the aid of vibriones.—*Amer. Jour. Pharmacy*, Feb., 1889.

Food for Shipwrecked Seamen.

The Prince of Monaco lately read a paper before the French Academy of Sciences, in which he said that shipwrecked seamen who have to take to the boats without provisions on the high seas can obtain food from the ocean itself by trailing a drag net made of any light stuff along the surface during the night. The net will, in the morning, be found to contain some small shell fish available for food. In the sea to the west of the Azores, the Prince added, the vegetable matter on the surface teems with animal life and fish which are capable of affording substantial nutriment.—Phila. *Ledger*, Feb. 11, 1889.

Eczema of the Anus and Genitalia.

In the *Deutsche med. Wochenschrift*, Jan. 17, 1889, the following method of treating eczema of the anus and genitalia is given: Hot sitz-baths, and washing with soapy water, followed by inunction twice a day of

℞	Cocain. oleat.	4–10 parts
	Ol. olivæ	20 "
	Lanolin	100 "

—Dr. C. Meymott Tidy has been awarded the Swiney prize, consisting of a silver cup and 100 guineas. It is given by the Society of Arts and the Royal College of Physicians of London conjointly, for work in jurisprudence.

—The hospital of the Johns Hopkins University will be formally opened May 1. Its organization has been entrusted to President Gilman, who, it is said, will reside in the hospital and exercise a close personal supervision over its executive management.

NEWS.

—Dr. J. W. Cox, of Pine Bluff, Arkansas, was shot in that place, Feb. 12.

—Dr. J. B. Taylor died while attending a patient in East Cambridge, Mass., Feb. 15.

—Dr. Herman von Meyer, Professor of Anatomy in Zurich, has just died, at the age of seventy-four years.

—Boston physicians have been ordered to make a monthly return of the number of births attended by them.

—Dr. Henry F. Formad has withdrawn his resignation as Demonstrator of Pathology in the University of Pennsylvania.

—A disease described as resembling membranous croup is reported to be raging among the children at Wabash, Indiana.

—The William F. Jenks Prize for the best essay on the "Diagnosis and Treatment of Extra-uterine Pregnancy" has been awarded to Dr. John Strahan, of Belfast, Ireland.

—Dr. D. W. Cheever has given $5,000 to the Medical Department of Harvard University to establish a scholarship to be known as the "David Williams Cheever Scholarship."

—Dr. Francis B. Kane, Professor of Clinical Medicine in the Medical Department of the University of California, died recently in San Francisco of pneumonia, after a very short illness.

—Dr. F. G. Mitten reports a case to the Cincinnati *Lancet Clinic*, Feb. 16, in which he suggests that a certain deformity, which is present in a child five months old, is due to a supernumerary clavicle.

—Dr. Carl Zoller, of Philadelphia, has been bound over by United States Commissioner Bell to answer the charge of sending obscene postal cards to the Medico-Jurisprudence Board of Pennsylvania.

—The New York Postgraduate Medical School and Hospital has obtained a lease for ten years of the property adjoining its present location, and will use the addition for increasing the babies' wards of the Hospital.

—The *Chemist and Druggist*, Jan. 26, says that a pharmacist in Warsaw was recently making up a prescription consisting of 32 parts of chlorate of potassium and 4 parts of tannic acid, and on adding a few drops of oil of peppermint to flavor it, the mixture exploded with great force, doing considerable damage. A St. Petersburg pharmacist has dispensed the prescription with the same result.

HUMOR.

"GEORGE, dear, what kind of fruit is borne by an electric-light plant?" "Electric currents, of course."—*Terre Haute Express.*

WHAT "FAMILY PHYSICIAN" MEANS.—"Who is General Bickett's family physician?" was asked of a doctor. "I guess I am," was the reply; "at least, he owes me three hundred dollars."—*Puck.*

A NEW WAY OF DIAGNOSTICATING SHOULDER PRESENTATION.—Quiz Master—How do you diagnosticate a shoulder presentation? Student—By feeling for the hair in the axilla.—*Medical Record.*

MINISTERIAL RISK—"I'm very glad to have been of any comfort to your poor husband, my good woman. But what made you send for me, instead of your own minister?" "Well, sir, it's 'typhus' my poor husband's got, and we dinna think it just reet for our ain minister to run the risk!"—*Punch.*

PRECAUTIONARY.—Quilpin—"And now, sweetest, what kind of an engagement ring will you have? Shall it be a diamond?" Sweetest (hesitatingly)—"O, Algernon, pardon me, but—but—" Quilpin—"But what love?" Sweetest—"You newspaper men have so much to do with paste, you know, that—suppose you let me go with you when you select it?"—*Burlington Free Press.*

HISTORIC JOKES.—Napier's famous despatch from India announced his victory in one word, "Peccavi"—which is, by interpretation, "I have Scinde." Very much of the same kind was Gen. de Bourmont's message to the French War Minister in 1830, when the Dey of Algiers escaped him after being taken. "Perdidi Diem"—"I have lost a Dey." It is said that Drake, when the ships of the Armada turned their sails, sent to Elizabeth the word "Cantharides"—that is, "The Spanish fly." This last is probably a fable.—*Temple Bar.*

"WHAT a QUICK-TEMPERED FELLOW Gapeleigh is!"

"Why, what has he been doing now?"

"We were at dinner the other day, and Gapeleigh—who never has any use for a fork, you know—was quite in earnest in what he was pleased to call the unreasoning prejudice against the knife at table. He contended, with much warmth, that the knife was the proper thing to eat with. It was the most convenient, every way—at least, he found it so."

"Well, and what then?"

"Oh, I simply remarked that all persons were not gifted with a mouth like the mouth of a river; and, if you'll believe it, Gapeleigh took it as a personal affront, and he hasn't spoken to me since. But then he's so quick-tempered it's hard to get along with him, any way."—*Boston Transcript.*

OBITUARY.

MARY H. STINSON, M.D.

Dr. Mary H. Stinson died at Norristown, Pa., Feb. 11, of erysipelas. She was born on November 14, 1819, and was therefore in the 70th year of her age. After studying at the female seminary in Charlestown, Mass., she studied medicine and was graduated in the class of 1869, from the Woman's Medical College of Pennsylvania, the Faculty of which College recommended her for the position of assistant physician in the department for women at the Massachusetts State Lunatic Hospital at Worcester, a position to which she was elected by the Trustees in July, 1869. This was the first appointment of a woman to such a position. In 1875 Dr. Stinson resigned, and the next year visited Europe to make a study of the manner of conducting the hospitals for the insane and the sick, and the medical departments of the universities. When the Hospital for the Insane for the Eastern District of Pennsylvania was organized at Norristown, she was offered the position of resident physician of the Women's Department, but declined it.

JOHN C. DALTON, M.D.

Prof. John C. Dalton, of New York, died Feb. 12. Dr. Dalton was born 64 years ago in Massachusetts, and was graduated from Harvard University in 1847. He served successively as Professor in the Medical Departments of the Universities of Buffalo and Vermont, and of the Long Island Hospital College, and in 1855 began his long service with the College of Physicians and Surgeons of New York, a service broken only by his term in the army, where he became brigade surgeon. He was the author of the well-known text-book on physiology. He was the first in this country to teach physiology with illustrations by vivisection. In the International Medical Congress, held in Philadelphia in 1876, Dr. Dalton was a delegate from the American Medical Association, and was chosen President of the section on Biology.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

LECTURE.

FAILURE OF VISION IN OLD AGE.[1]

BY EDWARD JACKSON, A.M., M.D.,
PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC.

It is a general law that the more highly differentiated or developed an organism or an organ, the more liable it is to injury by violence from without, or defect of nutrition from within. From this liability the delicate and complex visual apparatus is not exempt. It is universally understood that some sort of loss of visual power is a necessary condition of old age; but few appreciate how often remediable conditions are taken as part of the inevitable, and submitted to without any attempt to get relief.

The conditions causing impairment of vision coming on with age might be grouped under two heads: physiological, those arising in what must be regarded as a strictly normal course from development to dissolution; and pathological, or those diseases to which age renders the eye especially liable. But between the two groups no hard and fast line can be drawn. There are conditions, such as senile nerve-atrophy and cataract, which, though commonly classed with diseases, are so closely allied to the normal senile degenerations, that the placing of them in the one group or the other would seem to depend mainly on the age at which they occur, or the relative advancement of other processes of bodily decay.

Failure of Accommodation.

Among physiological conditions, most important is failure of accommodation, beginning in infancy and almost complete at the period when other senile changes are fairly begun. Primarily the loss of power to focus the eye for near objects depends on increased rigidity of the crystalline lens. The lens, jelly-like and extremely elastic in infancy, becomes progressively harder and

[1] One of the Tuesday Evening Lectures, delivered at the Philadelphia Polyclinic.

less elastic year by year. So that while during adolescence the ciliary muscle actually increases in strength, its power of changing the shape of the crystalline lens and rendering it more convex steadily diminishes. As the process continues the near point of perfect focussing, and distinct vision, recedes; until between 40 and 50 years, in the normal course of the change, ordinary close work, such as reading, writing, sewing, etc., is interfered with, and *presbyopia* is said to begin. Yet even when this occurs there may still be no diminution in the muscular power brought to bear on the crystalline lens, but simply an increased resistance to any change of shape. Later when the power of accommodation has been still farther diminished, so that what remains is of but little practical importance to its possessor, and he comes to rely on glasses for any change of focus, the ciliary muscle often undergoes atrophy, caused or accelerated by disuse; and the remnant of accommodative power is entirely lost. After this failure, which for all emmetropic and hyperopic eyes has necessitated the wearing and frequent strengthening of glasses, is complete, there can be no farther loss of sight from this source. It is popularly regarded as remarkable that a person of eighty or ninety should be able to read with the same glasses as he wore twenty or thirty years before; but really the failure that glasses were sought to make good, is commonly complete at sixty, and unless the eye is changed in some other respect, no other glasses could be so satisfactory.

Senile Ametropia.

The loss of the power of accommodation does more than simply interfere with the seeing of near objects. While emmetropia is the standard aimed at in the development of the eye, few eyes accurately attain it. In nearly all there is present a perceptible amount of ametropia, usually in the direction of hyperopia; which the power of accommodation enables one to correct. This power being gone the ametropia becomes absolute, and distant vision also becomes imperfect. Hence the large majority of persons, through changes strictly physiological, suffer some failure of vision with age. But this failure can in a manner be compensated by the use of glasses.

The same compensation is available in the case of ametropia not formerly present and unmasked by loss of accommodative power, but arising from senile changes in the form or refractive power of the cornea or lens. Such ametropia generally takes the form of hyperopia, the so-called "H. acquisita"; but in quite an important class of cases there is an increase in the refractive power of the lens leading to myopia. These latter are the cases of "second sight." After having been compelled for years to wear convex glasses for near vision, they discover that they can again read with weaker lenses, or without any such aid at all. But this does not come through any recovery of power to change the focus of the eye, but through a gradual shifting of the point for which the eye is adjusted, from a distance to somewhere about the point at which objects are commonly held for near vision. The adaptation for near-seeing is gained by loss of distinctness in far-seeing. These same senile changes of the crystalline lens occasionally give rise to considerable degrees of regular astigmatism; and very generally in their more advanced stage cause irregular astigmatism. These same changes, carried but a little farther, result in opacity of the crystalline lens, or cataract.

Cataract.

This condition is of importance, not only because it is common and often causes the loss of all useful vision, but especially because its management often requires the reversal of the rule which applies to all other conditions likely to cause blindness. In other conditions treatment does most good, or only does good, when commenced at the earliest possible moment. In cataract radical treatment can be resorted to only after a longer or shorter period of delay. If, as happens not rarely, a diagnosis of cataract is made when the failure of vision is really due to something else, the patient is likely to be advised to enter upon a course of waiting which never can do any good, and that may consume the precious time, during which alone therapeutic measures could have been resorted to with any chance of benefit. On this account, I hold that every one offering himself to the people as a general practitioner of medicine or surgery, and undertaking to give any opinion as to a failure of sight, should be able to recognize with certainty whether, in any given case, cataract be, or be not, present to such extent as probably to cause the given impairment of vision.

Among methods that may be employed for the recognition of cataract, that of simple inspection, or inspection under the most favorable conditions, called *oblique illumination*, may be mentioned, only to state that no reliance whatever should be placed

upon it. The experienced ophthalmic surgeon knows that while in some cases he can recognize cataract in this way, that any senile eye with a dark enough choroid, and large enough pupil, will present a striking appearance of opacity of the lens, although the lens may be absolutely normal and transparent. So that the largest experience will not enable him to judge whether it really is a case of cataract or not. Again, there are some cataracts, so-called black cataracts, in which the appearance of the pupil is quite normal. And even in ordinary forms of cataract, if the pupil be small and the opacity not immediately beneath the pupil it may not, in this way, be possible to recognize its presence.

The diagnosis of cataract is generally to be made with the *ophthalmoscope*. But by ophthalmoscope I do not mean any elaborate or high-priced instrument. The cheapest, the common "Liebreich" form, which cannot be spoken of as *good* for any thing else, answers this purpose as well as the most costly. The perforated concave mirror commonly used for illuminating the ear, nose, or throat, answers admirably; or, lacking all these, any piece of looking-glass with a little opening scratched in the silvering will be found quite satisfactory. Throwing the light into an eye with the ophthalmoscope, held ten or twelve inches distant, and placing his own eye at the aperature in the mirror, the observer sees the pupil of a normal eye occupied by a uniform red glare, paler in persons having a light choroid, or when the optic disc comes opposite to the observer, and more dusky as the choroid is darker. When however cataract is present, this red glare from the fundus of the eye is interrupted. If the cataract be advanced toward maturity, no red light from the fundus is perceived by the observer; but if even the smallest speck of lens substance has become opaque, it will appear as a black spot very noticeable against its brilliant red back-ground. Specks of opacity in the cornea, or upon the lens capsule, may cause the same appearance; but if the observer will move his position up and down, or from side to side, specks in the lens will seem to move across the pupil in the same direction as he moves, those in the cornea will seem to move in an opposite direction, and those on the lens capsule will appear to remain stationary. In the very few cases in which the ophthalmoscope does not entirely settle the diagnosis as to cataract, the *catoptric test* may be resorted to. In it we look for the little and rather faint inverted image, formed by the posterior surface of the normal lens, of a candle-flame held before the eye. We recognize this inverted image in this way. The cornea always gives us a bright erect image of the flame; and the inverted image we seek is situated on the opposite side of the pupil, and on moving the candle, while the corneal image moves with it, the image in question moves in exactly the opposite direction. Of course any opacity of the lens or its capsule prevents the formation of any such image.

You must not regard the certain recognition of the presence of lens opacity as completing the diagnosis of cataract. It only begins it. Many old people have some opacity of the crystalline lens, whose impairment of vision is due, perhaps entirely, to other causes. For cases occur in which, with very marked opacity of one portion of the lens, other portions are so little affected that the vision remains normal, or very nearly normal. But on the other hand, when the lens by its opacity gives evidence of damage by imperfect nutrition, it does not generally suffer alone. As a rule other parts of the visual apparatus suffer with it; and to their impaired function the lowering of vision may be due, quite as much as to cataract. So, while it may be quite unjustifiable to make a diagnosis of cataract when there is no cataract, it may be almost as bad for the patient to rest on the diagnosis of cataract, even though it be present, if along with it some other unrecognized lesion exists, which is equally or to a greater extent the cause of the impairment of vision. One other point about cataract is to be remembered, namely, its extreme frequency. After a certain age a majority of eyes present some lens opacity; and in extreme old age it is quite general; but the majority of persons die before the opacity has involved enough of the lens to deprive them of useful vision.

Glaucoma.

An affection frequently confounded with cataract, and always with most disastrous results, is glaucoma. In it the pupil is commonly rather large, and the lens looks gray, or greenish and partially opaque, to simple inspection, even though it is perfectly clear. The essential fact of the disease is increased tension or hardness of the globe. It occurs after middle age; and this has been ascribed to the increased size of the lens, which continues to grow throughout adult life. It is supposed that the lens pressing on the periphery of the iris hinders the out-flow of fluid from the eye, and thus causes the

increased tension. The course of the malady is invariably, unless checked by treatment, toward absolute blindness, usually with great pain in and about the affected eye. But its progress is often very insidious and deceptive. Exacerbations occur during which the sight grows suddenly worse, followed by partial recoveries during which some of the visual power is gradually regained. The patient is inclined to hope that each "relapse" may be the last, and may be followed by more complete recovery; and fails to realize that each is a positive advance of the morbid process covering ground never to be regained, and with an ever increasing tendency toward accelerated movement. These exacerbations are commonly attended with pain and hyperemia of the globe, which ought to distinguish the affection absolutely from cataract, but which are too often ascribed to "neuralgia" and a "simple inflammation" of the eye-ball. Glaucoma is not a very common affection; but its strongly malignant tendency gives it a great claim on the attention of the general practitioner.

Passing over certain other pathological conditions which might claim notice here, such as albuminuric retinitis, and a form of chorio-retinitis that might well be designated as senile, as of comparatively less importance, let me call your attention especially to

Senile Amblyopia and Atrophy of the Optic Nerve.

Of course, I use the term amblyopia in its modern sense, to designate imperfect vision, which cannot be accounted for by any fault of refraction, or pathological process making itself manifest in any other way. The impairment of function must in such a case involve some portion of the nervous apparatus concerned in the act of seeing. Amblyopia occurring in old people is often to be regarded as strictly physiological, as merely a part of the general diminution of capacity of the organism to respond to external stimuli, which constitutes a true decline of life. Often the amblyopia is accompanied by or depends on a lessened blood-supply of the parts, which is shown by a pallor of the optic disc; and in many cases this local anemia is but part of a lessening of the general blood-supply, another kind of vital decline. But marked amblyopia may exist without perceptible local anemia, and a very noticeable pallor of the disc is not incompatible with perfect acuteness of vision. When both pallor of the disc and impairment of vision are especially well-marked, the case may be regarded as one of optic atrophy. In cases of atrophy, however, there is also contraction of the field of vision. In senile atrophy, this contraction is concentric and most regular, and is especially great for color vision, red and green being distinguished only in the immediate vicinity of the fixation point.

A point which I wish in this connection especially to impress upon you is that you should not conclude that any given case is one of merely senile, or irremediable amblyopia, or nerve atrophy, until all other possible explanations of it are proved unsatisfactory. My experience indicates that in old people with inferior blood-supply, with diminished power of resistance, with lessened capacity for repair, the nervous portion of the visual apparatus is especially susceptible to the actions of certain substances that influence it injuriously, such as tobacco, lead, quinine, large doses of the bromides, etc.; and that these agents may produce amblyopia or atrophy, even though they are taken only in amounts that have previously produced no injurious effect whatever. For instance, I have now under observation a man, 60 years old, who had used tobacco very moderately, and only a little alcohol occasionally, ever since he was a boy, and who is using less now than in earlier years. His sight had been failing for six months, and was less than half the normal. Stopping the tobacco and alcohol, and taking full doses of strychnia gave him full vision within a month. Had I rested in a diagnosis of senile change, probably neither my patient nor I would have been the better off for our coming together.

—The *Medical Press and Circular,* Feb. 6, says: Fears have been expressed lest the Paris schools should be overrun with foreign students, and it would even seem that endeavors have been made to impose certain onerous restrictions on their attendance. A recent number of the *Revue Scientifique* contains a very eloquent protest against so unworthy a sentiment, especially on the eve of an international exhibition. The prestige of the ancient Faculty of Paris would suffer sadly were foreign visitors to be driven away, and its influence as an intellectual centre diminished. University teaching in France is practically free to all comers, and it is one of its most noble attributes. It is satisfactory to find that the *Chauvinists* are not likely to have it all their own way.

COMMUNICATIONS.

PRACTICAL ASEPTIC SURGERY.[1]

BY J. W. LONG, M.D.,
RANDLEMAN, N. C.

Mr. President and Gentlemen: On this occasion I hope to speak not so much *to* you as *through* you to the great body of patient toilers throughout the South. Southern doctors are beset by many trying difficulties. In the first place, most of them are dependent upon their practice for a living, while many have large families to support; besides, those of us who do not live where we are accessible to a drug-store are compelled to furnish our own medicines and surgical supplies. Add to these difficulties broken-down health—which is often the case—from overwork and exposure, and, I am sorry to say, sometimes from dissipation, and is it any wonder that the average Southern doctor buys so few new books and periodicals and so seldom reads them when he does get them? The subject which I shall endeavor to present to you to-day has invited so much speculation and given rise to so many varying methods, each claiming to be the right one, that our minds have become confused and we overlook the principles involved by considering the hypotheses and paraphernalia incident to the subject. If I can even to a small extent strip this great question of some of its extravagances and impracticabilities and present it to you in a practical everyday form, then I shall count myself most happy.

We all know that in these latter days the *technique* or management of accidental and surgical wounds is entirely different from what it was one or two decades ago. Formerly the operator expected suppuration; now he is disappointed if it occurs. Then surgical fever followed almost every operation as a matter of course; now its presence indicates some defect in the management of the wound. Aseptic surgery has come to be the order of the day, and it simply means surgical cleanliness as applied to the treatment of wounds. Aseptic surgery has made dangerous operations safe, and legitimized many heretofore unjustifiable procedures. It is the outcome of common observation that devitalized animal tissues when brought under favorable conditions putrefy. These favoring conditions are warmth, moisture, and certain micro-organisms. The absence of any one of these conditions will prevent the fermentive changes which in the living animal result in suppuration and septicæmia. Now I am not here to champion asepsis, nor to dispute with any one the validity of its principles, for I consider that these have already been established upon an immutable basis; and he who does not believe in aseptic surgery must necessarily believe in septic surgery. Notice, please, that I did not say *anti*septic but *a*septic; for antiseptics are only methods, while asepsis is a science involving great and unvarying principles: the one may change, the other never. Carbolic acid and corrosive sublimate may be forgotten, iodoform may be relegated to the realms of obscurity, but surgical cleanliness will ever be counted the greatest safeguard to life and health that man has yet devised.

The object of this paper is purely practical, and the hope is earnestly entertained that aseptic surgery may be set forth in such a light, stripped of all technicalities as well as of all unnecessary expense, that any regular doctor possessed of a fair knowledge of anatomy may at comparatively small cost fit himself to do in an aseptic manner all the operations which occur in every-day practice. After having once tried aseptic surgery and mastered its principles, I am sure no conscientious man will ever go back to the old ways of long finger-nails and rusty instruments.

To this end I have devised two bags, the smaller of which is my daily companion, the larger being used only in the more important operations. Prof. Gerster presented to the New York County Medical Society a bag to be used in "surgical emergencies," and while it is a capital thing, it is not adapted to the everyday work of the average practitioner. My larger bag is somewhat like his. I have been led to the construction of these bags by the repeated annoyance which arises from not being prepared to do the operations, great and small, that constantly come up in my practice. Not only has this been true of myself, but I know numbers of good men who believe in asepsis and antiseptics, and would like to do their operations aseptically, but they are not prepared to meet the emergencies as they arise, and they go along in the old slip-shod way. Furthermore, they are deterred from trying to get ready by the controversies and mystery which surround the subject and the supposed great expense of the necessary appliances. As a matter of fact, I do not know of one man in fifty who

[1] An address delivered before the Southern Surgical and Gynæcological Association, Dec. 4, 1888.

is prepared at any moment to amputate even a finger, or do a herniotomy, or any other operation in an aseptic manner.

The rules and formulæ of aseptic surgery are simple but comprehensive, and may be briefly stated as follows:

The proper cleansing of the surgeon's hands and arms and the parts to be operated on deserves the first consideration. The surgeon's coat should be removed, his sleeves rolled above the elbows, the finger-nails carefully pared and all dirt removed from under them by means of a sharp-pointed pen-knife. The hands and arms should then be scrubbed and soaked in hot water and soap. Lye soap is preferable because of its solvent properties. The hands ought to be kept in the water for at least five minutes, that the hard places and crevices may become thoroughly softened and cleansed. A stiff nail-brush is indispensable in cleansing the hands. After this the hands and arms should be placed for one minute in a solution of corrosive sublimate, 1 to 1000. During the operation a basin containing a similar solution is placed convenient to the operator, who dips his hands into it whenever he chances to touch anything that has not been sterilized, as a chair, his nose, a sponge picked up from the floor, etc. This same care of the hands is required of all the assistants. Surgical cleanliness means more than some people imagine. I remember seeing a doctor, who does a large amount of surgery and who professes to believe in and practice antisepsis, apply an ointment to the lids in a case of syphilitic conjunctivitis, then examine and make application to a case of hemorrhoids, catheterize a patient, and finally operate for double pterygium—all without washing his hands either before, during, or after treating these several cases. As Gerster says, "the new surgery of cleanliness does not tolerate pretense and imposition."

If possible, always have the patient bathe and change his clothing before an operation. When on the table the parts to be operated on must be carefully cleansed with hot water and soap, shaved, and finally washed with sublimate solution, 1 to 1000. Towels wrung out of a warm sublimate solution should be arranged around the field of operation.

It is impossible to do work aseptically with instruments that can not be rendered aseptic. The ingenuity and workmanship displayed in complicating instruments is simply wonderful—double joints, screws, rough handles, and every other device imaginable to make an instrument difficult or impossible to be cleaned. I am glad to note that modern surgery is demanding instruments more simple in construction, the revolution exhibiting itself in open joints and hard-rubber handles. An instrument should have as few joints as possible; most jointed instruments can be made with one joint, and this must be an open joint, either like the American bullet forceps, which have the French joint, or the Jones joint. Very few instruments indeed can not be made to come apart easily. Toothed instruments should have coarse teeth, with the angle between the teeth obtuse and rounding, so that all particles of matter may be readily dislodged by a stiff nail-brush. Those instruments not having solid metal handles should have baked-rubber handles. Such handles will withstand the effects of boiling water, which is the best medium for cleaning instruments. Wooden handles or rough handles are entirely unsuitable and should be discarded. Even the name of the manufacturer should not be stamped on an instrument. The Sims' dull curette is a beautiful example of an aseptic instrument, while the sharp curette is a typical example of a non-aseptic instrument. Horn handles like this scalpel are objectionable, as hot water causes the sides to spring away from the metal shank, leaving crevices in which particles of matter may lodge; we can never be sure they are clean. The Volkmann scoop is also perfectly aseptic, while the periosteal elevator is "a thing of beauty and a joy forever." These instruments were selected at random, and presented simply to show the difference between the perfect and faulty. I have been thus careful to particularize concerning the make-up of instruments for the reasons given above, and the additional fact that there is not a single pocket or operating case on the market, so far as I know, which meets the requirements of modern aseptic surgery. Every surgeon should select each individual instrument—don't buy anybody's "case," and see to it that in every respect each one is genuinely aseptic.

The care of instruments is an important item and has given me much concern. Half an hour before an operation they should be placed in a five per cent. solution of carbolic acid. For small operations a shorter time and a three per cent. solution will do. Knife blades remain in the solution only a few minutes, as the acid dulls

the edge. Immediately after an operation place the instruments in a pan and pour very hot, even boiling, water over them. They should then be scrubbed thoroughly with soap and a brush, and dropped back into the carbolic solution, from which they are taken and dried with a soft cloth. It is very necessary that all toothed instruments be carefully brushed with a stiff nail brush in order to remove particles of blood and *débris* which invariably lodge between the teeth. For transportation instruments should be wrapped in a clean towel, or placed in canvas case, as either can be washed, but a leather case can not be washed and causes instruments to rust. No rust speck should be tolerated. The rust must be removed or the instrument laid aside. For permanent keeping a dust-proof drawer or case in a dry room is the best place to prevent instruments from rusting.

I am constrained to specify the care of catheters, because of the imperfect manner in which they are usually cared for. Before using, the cleansed catheter should be placed in three per cent. carbolic solution; a 1 to 1000 sublimate solution may be employed for rubber catheters. In either case, transfer the instrument to a solution of common salt 6 to 1000 (heaping teaspoonful to the quart of water, previously boiled), after which anoint them with iodoform ointment (gr. viii to ℥i). After being used in a septic case soft rubber and woven instruments should be destroyed. To cleanse rubber catheters, wash them in hot water and soap, and flush by means of a small syringe; then wash and flush in a five per cent. carbolic solution. Metal catheters can be properly cleaned only by prolonged boiling (an hour), or by passing through an alcohol flame until all smoke and steam cease to issue from them. An observance of these precautions will greatly lessen the number of cases of urethral fever and catarrh of the bladder.

If we could always have our hands, instruments, the parts to be operated on, the atmosphere, etc., in the ideal aseptic condition, there would be no need of germicides; but, unfortunately, we can not be sure of this happy condition. Therefore we resort to the chemical antiseptics, by means of which we keep a wound aseptic, or render it so by sterilization.

Antiseptics.—For irrigation, disinfecting hands, preparing sponges and gauze corrosive sublimate is the best and most convenient germ-killer. For the hands, arms, and the parts to be operated on, solutions of the strength of 1 to 1000 are necessary; while for irrigating ordinary wounds solutions of from 1 to 2000 to 1 to 5000 are strong enough. Irrigation of the greater cavities require the solutions to be of only 1 to 8000 to 1 to 20000 strength. The following formula will answer every purpose:

℞ Corrosive sublimate . . . . . ℥i
Water . . . . . f℥ii

M. S. Teaspoonful to one pint of water = 1 to 2000.

Some add twenty grains of common salt to the above formula, which prevents the mercury from decomposing so soon. Tablets of corrosive sublimate containing the proper amount to be added to a pint of water may be purchased from any manufacturing chemist or large dealer. They are more convenient, but more costly than the salt prepared as above. In all solutions boiled water is preferable, but not indispensable, in the majority of instances.

For disinfecting instruments and keeping sponges aseptic, carbolic acid excels any known agent. A five per cent. solution is made by thoroughly mixing one ounce of the acid with one and one quarter pints of water; a three per cent. by adding one ounce of acid to two pints of water.

The Thiersch solution consists of boracic acid ℥i; salicylic acid gr. xv; water Oi. This solution may be used with impunity in the abdominal cavity or elsewhere, as it will cause no irritation.

No surgeon can afford to be without iodoform. Its desiccating properties render it invaluable in the treatment of the vast majority of wounds, both accidental and surgical.

I have given but a few of the well known germicides, for the reason that if we thoroughly understand the use of a few they may be made applicable to every case, and such knowledge is preferable to having an imperfect knowledge of many. Besides, it relieves the mind of the tedium and strain incident to frequent changes; for when one habituates himself to the use of any particular thing, its application becomes a matter-of-course and requires little thought.

Sutures.—Silver wire may be kept wrapped in protective or in a metal cylinder. The cylinder is costly and not indispensable. Silk may also be kept wrapped in the protective. Both silver and silk are rendered aseptic by placing them in a three to five per cent. carbolic solution for half an hour, or by boiling for an hour. Cat-gut is made

aseptic by soaking in the so-called oil of juniper berries[1] for twenty-four hours, then transferred to ninety-five per cent. alcohol; or it may be kept in the oil indefinitely. The bottle contains spools holding gut of several sizes, the ends passing through a perforated stopper, and any desired amount may be drawn from the bottle without removing the spools.

The best drainage tubes are of soft black rubber, with a lumen of one-sixteenth to one-half inch. These may be kept in a tightly corked glass jar dry, or in a five per cent carbolic solution. Bone drains are useful in permanent dressings and are kept immersed in oil of juniper berries.

Dressings.—To prepare sublimate gauze, divide say twenty-four yards of cheese cloth into four pieces. Double each piece several times, and tie a string around it. Place these pieces in water with two pounds of bicarbonate of soda and boil for an hour or more. Then rinse the cloth through clear water and place it in a solution of corrosive sublimate, 1 to 1000. After twenty-four hours it may be wrung out and hung up in a dustless place to dry. For permanent keeping, either a stout jar, tight drawer, or a can with the lid held down by adhesive plaster will do. Excellent prepared gauze may be bought at about fifteen cents a yard; but it can be made by any one disposed to try at a cost of only about four or five cents a yard.

Iodoform gauze is made by sprinkling gauze freshly wrung from a 1 to 3000 sublimate solution with iodoform from a pepper box; Gerster's, or an ordinary tin box with perforated top, will answer.

Absorbent cotton can be purchased at small cost, or can be prepared in an emergency by dipping cotton batting in a fifteen per cent. boric acid solution (boracic acid ʒv, water Oii).

Protective is thin rubber tissue and costs about fifty cents a yard.

Bandages, both cotton and flannel, should be made from cloth previously treated as described for gauze. As a matter of economy a cigar-box will make an excellent bandage roller. Near one end pass a stiff wire through from side to side, and shape one end of the wire into a crank. Toward the other end of the box arrange three or four wires or rods so that the cloth will pass over and under them in succession. Every operating case should have one or two rubber bandages.

Sponges.—Florida sponges are cheap and are better than the fine silk ones. They are beaten well and washed to remove all grit; soaked for fifteen minutes in dilute muriatic acid; thoroughly kneaded in hot water and soft soap; rinsed through clear water till they loose the soapy feel; finally transferred to a five per cent. carbolic solution, where they may be kept indefinitely. After use in an aseptic case sponges are cleansed by repeated washings in warm—not hot—water, and immersion for one hour in 1 to 500 corrosive sublimate solution. Never use a sponge that has been used in a suspicious case, nor to dress a wound with; pellets of cotton are infinitely better and can be destroyed when once used. I have seen one little sponge do service in every case occurring in the practice of a distinguished (?) surgeon.

The irrigator is indispensable, the ordinary fountain syringe being one of the best for a surgical bag. On a pinch, the irrigating fluid may be poured from a pitcher.

In considering the types of dressings we will notice just three with their modifications; and these keep the wound in an aseptic state by desiccation, sterilization, or hermetical sealing of the surfaces, or by two or more of these principles combined.

Desiccation.—Small wounds, especially about the face and neck, may be kept aseptic by freely dusting them with iodoform, or equal parts of iodoform and subnitrate of bismuth. These drugs, especially the former, have the peculiar property of drying a wound by checking the secretions, while the secretions that do escape are rapidly desiccated to a pasty crust, which protects the wound from contamination by infectious substances and in turn is rendered aseptic by the antiseptic properties of the powders. When there is much oozing the parts should be dusted every half-hour until a crust has formed.

Sterilization.—By this is meant the moist dressing. The wound is gently packed with gauze squeezed from a fresh sublimate solution, 1 to 1000 to 1 to 2000. The field of operation and contiguous parts are lavishly padded with gauze and cotton previously treated as above, the whole being covered by a piece of protective, held in place by a roller bandage. This dressing will absorb discharges more readily than the dry dressing, and is applicable in cases in which we may expect profuse oozing or fear the drainage tubes will become clogged. When no

[1] In a private note from Dr. Squibb he says: "The best oil of juniper berries in the market is obtained by distilling the fresh twigs of a different variety of juniper from that which bears the berries."

impervious outer dressing can be had, the gauze may be kept moist by pouring a drachm or two of an antiseptic solution into it every half hour.

Desiccation and Sterilization.—These two types of dressing are happily confined and modified in the *dry dressing*, in which the wound and parts around are thickly covered with gauze and cotton, previously sterilized by chemicals. A few strips of iodoform gauze are laid directly over the line of incision to facilitate the drying of the deepest portions of the dressing. No protective is applied to the outside, as the free access of dustless air is necessary to hasten the drying process.

Schede's modification of the dry dressing.—The prime object in this dressing is organization of the blood-clot. Asepsis must be perfect. A piece of protective just a little larger than the wound is laid directly on the parts, and iodoform gauze thickly applied above this. No protective is used on the outside of the dressing.

Hermetical sealing of the wound.—I do not think any paper relating to the modern treatment of wounds complete that does not give credence to the hot water method, so ably promulgated by the late Dr. Varick. This is specially indicated in amputation wounds, and consists in applying water only a little below the boiling point to the freshly-cut surfaces until they are thoroughly glazed with a coat of albumin. This effectually occludes the mouths of all lymphatics and small vessels, including the capillaries, so that contamination is impossible. The parts are next brought together, and little dressing is applied. The success of this method is truly wonderful. Small wounds may be hermetically sealed by touching them with acetic acid.

(*To be continued.*)

A CASE OF MENINGOCELE.

BY CHARLES BAUM, M.D.,
PHILADELPHIA.

On September 18, 1888, I was summoned to attend Mrs. N—, æt. 37, American, of large frame, very fat figure, and nervous temperament, being in labor with her eighth babe.

Two abortions had occurred in her early married life. No history or evidence of syphilis could be elicited. At a preliminary visit she stated that in her former labors she had acted like a crazy person, screaming, pulling out her hair, striking her head and attempting to bite her attendants.

When I entered the room she was highly excited, walking the floor, wringing her hands and declaring she would "die this time." Her former children had been very large and forceps had been applied on one occasion to hasten delivery for the relief of nervous agitation.

Dilating pains had continued six hours. As the woman was in the act of placing herself in position for a digital examination, the amniotic fluid escaped with a gush. Upon examination, her pelvic diameters were found to be larger than normal, the os uteri was fully dilated and the finger came in contact with an elastic tumor, covered with the hairy scalp. Owing to obliteration of the usual fontanelles and sutures a right occipito-anterior position was determined by the relation of the ears to the swelling and the neck. The woman was at times entirely uncontrollable, but the labor pains were active and in two and a half hours the delivery was accomplished, manual assistance being demanded to liberate the shoulders and hips. Before the hips were delivered the child cried loudly. In deference to a superstitious notion of the mother, the extremely large male babe was not weighed, but was thought by the nurse to be about fifteen pounds; it surely weighed twelve pounds.

On the right side of its head was found an elastic, prominent tumor, which arose from the posterior fontanelle and extended along the sagittal and a portion of the lambdoidal suture. This entire region was bulging, while the edges of the occipital and parietal bones were everted about half-inch. Longitudinally over the prominence the measurement was 5¼ inches, transversely, 4¾ inches. Light was readily transmitted through the swelling. As the child grew, it was noticed that pressure upon the tumor caused drowsiness. In addition to this defect there was right sided scrotal hernia; otherwise, the child seemed healthy and natural in appearance.

To satisfy the demands of the parents, as well as to try the experiment, one gramme of potassium iodide dissolved in compound syrup of sarsaparilla and water was administered internally three times each day, and this was continued until the swelling was absorbed; locally, an application of ammonium chloride gr. xv, alcohol f ʒ j, was ordered to be made every six hours, but as was learned later, the parents made it every three hours.

By degrees the swelling disappeared, and on November 27, 1888, the bones were

united along the suture lines, there being, however, a general prominence, which has remained unchanged, over the region involved. Excepting slight constipation during the second week the child has remained perfectly well, never having displayed any nervous symptoms. At present it is teething easily, and was vaccinated January 24, 1889. He is large, fat, solid, bright, laughing and playful.

630 N. Broad St.

CASE OF SUB-SPINOUS LUXATION OF THE HEAD OF THE HUMERUS.

BY T. Y. SCOTT, M.D.,
BENTLEYVILLE, PA.

The reading of the report of Dr. Cate's case of sub-spinous luxation of the humerus, in the REPORTER of January 19, 1889, brings to my mind a similar case that occurred in my own practice, being the only case of sub-spinous luxation that I have met with in eighteen dislocations of the head of this bone. By referring to my note-book, I find the following particulars of the case, under date of Jan. 16, 1884:

Mr. J. C., æt. 70 years, a small man and very spare, apparently devoid of any adipose tissue, was thrown down while feeding his hogs by a large hog running against him from in front, tripping up his feet and pitching him forward, he alighting, with extended arms, upon his palms, while his feet were elevated in the air upon the back of the hog. I saw him within four hours after the happening of the accident. I found him sitting in a chair with the right arm resting upon pillows, and extending forward, slightly downward, and very slightly outward, the forearm flexed at a right angle with the arm. He was suffering much pain in the right shoulder. Examination of the shoulder showed no contusion or swelling, other than a hard rounded prominence on the posterior surface of the scapula, below the spinous process; absence of the head of the bone from the axilla, and a depression beneath the anterior portion of the acromial process. The sub-spinous tumor was firm, rounded and resisting, and its movements, in obedience to rotation and other movements of the humerus, were, owing to the marked scarcity of adipose tissue, very perceptible both to the eye and the finger.

In this particular case the prominence of the coracoid process was very marked.

Repeated attempts at reduction, both by manipulation and extension and counter-extension with the heel in the axilla, failed, but it was very readily accomplished by an assistant making extension forward, slightly downward and outward, while counter-extension was secured by means of a sheet carried over and down in front of the shoulder and brought back under the arm, traction being made with the two ends of the sheet widely separated, so as not to make pressure upward into the axilla, while I made pressure upon the head of the bone from behind forward toward the glenoid cavity.

Securing the arm to the side, with the forearm in a sling for two or three days, and the use of an evaporating lotion to the shoulder constituted the after treatment. The pain ceased with the reduction, and all the functions and strength of the joint were fully re-established in four weeks.

ACETIZED COTTON.

BY THOMAS W. HARVEY, M.D.,
ORANGE, N. J.

The value of acetic acid as a styptic is often forgotten. In its common form as vinegar, it is familiar to most every general practitioner as a ready means of controlling parenchymatous hemorrhages generally. The nose, gums, and uterus are the situations in which it has been frequently used.

I have recently had prepared by the lint-makers an absorbent cotton, impregnated with acetic acid, of three grades—5 per cent., twelve and one-half per cent., and twenty per cent. Cotton so prepared should be kept moist and be preserved in air-tight bottles. The advantages of the actetized cotton are that, while styptic, it is not corrosive and does not form sloughs; its taste is not unpleasant, and while the 20 per cent. cotton causes smarting when laid npon a denuded surface, yet it is not very irritating, and is antiseptic.

The conditions in which it will be found useful as a styptic are numerous. Some of these conditions are as follows: Epistaxis; hemorrhage from the gums after tooth extraction; in menorrhagia, as a tampon to be placed immediately at or within the os uteri; in cancer of the uterus—indeed in ulcerating cancer wherever located. It is also useful in prolonged flowing from a subinvoluted uterus, or from lacerations of the cervix or vagina after labor. It will control hemorrhage from organs such as the liver, when wounded by the separation of adhesions in

operations in the abdominal cavity—continued pressure for a few moments with the prepared cotton will stop persistent oozing that has resisted hot water and other measures, and which would require otherwise the use of the cautery and result in the formation of a slough.

I have not had sufficient opportunity to determine the relative values of the different cottons, but the stronger will act pretty sharply when there is an abraded surface on the skin. The twenty per cent. cotton may be used about the cervix uteri without pain, and also in many cancerous ulcerations.

The chief advantage of the acetized cotton is that it avoids the disadvantages of the iron styptic cotton now found in the shops.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, January 23, 1889.

The President, W. W. KEEN, M.D., in the chair.

DR. EUGENE P. BERNARDY read a paper on

Biniodide of Mercury—Its Antiseptic Use.

He first referred to his second paper "On the Value of Biniodide of Mercury as an Antiseptic in Obstetrics," read before the Philadelphia Obstetrical Society (April 1, 1886), and said that he had fully intended leaving the results of his investigations to the medical profession, and letting them, by further trial, confirm the correctness of his conclusions. As regards the solubility of the salt he said that in several papers on antiseptics, the biniodide of mercury is declared insoluble, and therefore difficult to use; in one paper, the cost is the objection, it being stated to be more costly than the mercuric chloride. It is to be sincerely hoped that pecuniary considerations will never interfere in the use of any medicine that will assist in saving a human life. The biniodide is rendered a soluble salt by the addition of iodide of potassium. After mentioning a number of references to the use of the biniodide in current medical literature, he reported several obstetrical cases:

Case I.—Mrs. L., aged nineteen, first pregnancy; was called to attend her (January 24, 1886) in a premature labor; she was pregnant about six and a half months; when I arrived, I found she had been delivered of a dead male child; the placenta came away in two hours; the patient did well up to the evening of January 27th, when she was taken with a chill, which was repeated in three hours; when I saw her on the morning of the 28th, her skin was hot and dry, face flushed, pulse 112, temperature 102°; tongue thickly furred, abdomen slightly swollen and very sensitive; lochia offensive. Ordered quinæ sulphatis, gr. xx.; morphiæ sulphatis, gr. ¼, night and morning; poultice over abdomen, and hot vaginal injections of 1 to 4,000 solution of the biniodide of mercury every four hours; at the second injection the discharges became free from any odor. January 29th, pulse 100, temperature normal. This treatment was kept up, with the exception of the large doses of quinine, to October 5th, when the injections were reduced to one a day for about four days, when the patient was discharged cured.

I have confined this patient since of a full-term, living child; the biniodide injections were used at once; she had a good lying-in; discharged on the ninth day, well. (The above case really belongs to my second series, but the manuscript was mislaid at the time, and found too late to be incorporated in my second paper.)

Case II.—Mrs. M., age thirty-five; fifth confinement; during her pregnancy she had worked very hard, doing almost the work of a man. Was called to attend her in labor, March 18, 1886; when I arrived at her bedside I found she had been in labor since the previous day; she appeared completely worn out, having hardly any strength to bear down; the family refused positively instrumental interference. I gave two doses of the fluid extract of ergot, teaspoonful, repeated in half an hour; under its influence the child was born; the placenta soon followed.

The patient did well up to March 24th, when, in the evening, she had a severe chill, which again occurred the following morning (March 25th). I saw the patient on the following day; she seemed to have aged fully ten years; her face was drawn, and of a deep yellow color, eyes bright and sparkling with delirium; pulse 140, temperature 105°; the abdomen was immensely swollen, and could not bear to be touched, more especially on the right side. Diagnosticated metro-peritonitis. Lochia arrested. Ordered quiniæ sulphatis, gr. xx., night and morning; morphiæ sulphatis, gr. ¼, whenever

pain was severe; hot poultice over the abdomen, hot vaginal injections of 1 to 4,000 solution of biniodide of mercury. March 28th, pulse 120, temperature 101°; lochia returning, abdomen not so sensitive. This treatment was continued up to March 31st; the abdomen now allowed of closer examination; in the right inguinal region could be detected a large mass; vaginal examination showed the uterus bound down and completely surrounded by lymph. Dr. W. Goodell, being called in consultation, verified the diagnosis. The biniodide injections to be continued; internally, quinine sulph., gr. iij., three times a day, besides an alterative tonic. The patient gradually recovered her health, without any additional treatment.

In this case the injections of the biniodide were constantly used for over a space of three weeks, first every four hours, then three times a day, then once a day, without the slightest systemic action of the drug occurring.

Case III.—On July 11, 1886, I was asked to see Mrs. W., in consultation with her family physician; on entering the house a most sickening odor struck my nostrils; it reminded me of uterine cancer in its last stage; the more I advanced, the worse the odor became; at last, I reached the room and bedside of the patient; of all odors, I never want to smell the like again; as the nurse remarked, it was worse than decayed carrion; how the patient lived through such a condition was simply miraculous.

I found she had aborted about two weeks previously, and had declined any interference in regard to extracting the placenta, saying "it will come away." On examination, I found the vagina full of sticky, horribly-smelling, broken-down placental tissue, the mouth of the uterus opened, the uterus full of the same kind of material as found in the vagina; the patient declined the use of any instruments, so I broke down and pulled out all that came within reach of my finger; I then washed out the uterus with a hot 1 to 4000 solution of the biniodide of mercury; not yet satisfied, I washed out the parts with another quart of the solution (1 to 4000), until the water came back clear.

I did not see the patient again, and, in answer to a letter to the attendant physician, I received the following:

"PHILADELPHIA, May 20, 1887.

"MY DEAR DOCTOR: I am glad to inform you that Mrs. W. did very well. The iodide of mercury pellets acted like a charm. There was no unpleasant odor attached to the discharges after we began their employment. . . . I have been an ardent advocate of potassium permanganate, but I am now a convert to the biniodide as an antiseptic."

Case IV.—Mrs. H., primipara, aged thirty, fell in labor November 18, 1886. On my arrival at her bedside, I found she had been in labor for some time, the mouth of the uterus wide open, bag of waters unruptured, vertex presentation. On making abdominal palpation, detected at once a twin pregnancy; after a somewhat lingering labor, the first child (boy) was born; on examination, I found the second child (girl) presenting with vertex left posterior; the head came down very slowly, and, on the solicitations of the patient and family, the labor was terminated with forceps. The patient did well up to the evening of the second day, when, about midnight, she was taken with severe frontal headache and chills. I saw the patient in the chill; half an hour after, her temperature was 104°, pulse 140; delirious; ordered quinine sulphat., gr. xx, at once, and repeat next morning. Next day (November 21), temperature and pulse the same, completely out of her mind; lochia almost ceased flowing, and what was present was offensive; abdomen extremely sensitive to the touch. Ordered the quinine to be continued, gtt. x. tr. digitalis four times a day; hot flaxseed-meal poultices over abdomen, hot injections in the vagina of 1 to 4000 biniodide of mercury every four hours. The following day, the lochia returned normal. The condition of things remained about the same up to November 25, when the symptoms were improved; the patient was discharged well, December 4, 1886.

(The following case was the first patient on whom I used the biniodide of mercury injections, and whose history is given in my first paper, June 4, 1885.)

Case V.—Mrs. D., third confinement (being compelled to leave the city, she fell into the hands of another physician), fell in labor September 6, 1886. After a lingering labor, she was delivered of a still-born child; on the second day, as far as I can learn, all the symptoms of an attack of puerperal fever set in; she remained very sick for several days. No vaginal injections of any kind were used. When I saw the patient, on September 19, 1886, she was suffering with an extremely tender abdomen, more especially on the right side, on which side could be detected a small lump. Vaginal exam-

ination disclosed the uterus partially surrounded by lymph. Discharges from the vagina very offensive. Pulse 100, temperature 101°-102°. Nothing could be retained on the stomach; as a drink, frozen champagne was ordered. Quinine sulphate, gr. x, once a day; equal parts of ungt. hydrarg. and belladonna to be rubbed over the abdomen once a day, followed by hot poultices, hot injections of the 1 to 4000 biniodide three times a day. My following visit found my patient improved, and in a week she was discharged, but it was some time before she regained her usual strength.

On November 1, 1887, I delivered the above patient, after an easy labor, of a large, female child; immediately after the placenta came away, I washed the uterus out with a 1 to 4000 injection of the biniodide; the injections were ordered to be used three times a day throughout the lying-in, which was perfectly normal, and the patient discharged, well and strong, on the ninth day.

Case VI.—Mrs. C., aged nineteen, first pregnancy; was called to attend her on the morning of August 19, 1888. After an easy labor, she was delivered in the afternoon of a large male child; the placenta came away in about twenty minutes. The following day the patient was doing well, but had not been washed, and the odor in the room was very disagreeable. On my following visit I found the patient in a high fever, temperature 103°, pulse 130, full and quick; tongue dry and chippy; the skin from the posterior part of the vulva back to beyond the anus was raw and covered with minute bloody points; abdomen very tender; lochia, what there was, was extremely offensive.

On close inquiry, I found that the mother of the patient, who was supposed to be nurse, had gone on a drunken debauch since the birth of the child, no doubt celebrating her "grandmotherhood"; the patient was placed at once in charge of a competent nurse; hot poultices were ordered to the abdomen; quinine sulph., gr. v, morphia sulph., gr. ¼, every four hours; hot injections in the vagina of 1 to 4000 biniodide of mercury every three or four hours, equal parts of zinc ointment and Goulard's cerate were applied over the raw surface.

August 24th, pulse 110, temperature 101°; lochia coming freely and without odor. August 26th, pulse 100, temperature 99°; 4 P. M., pulse 100, temperature 101°. Condition better, treatment continued; patient discharged, entirely cured, September 1, 1888.

With the three cases reported in my first paper, eight in my second, and the six cases just detailed, in all, seventeen (obstetrical) cases in which the biniodide of mercury had been employed, gives us, certainly, sufficient data to draw positive conclusions.

Abdominal Abscess Intercurrent with Typhoid Fever.—On April 20, 1887, I was requested to see Mary B., aged five years. The little patient had been ailing for the past week, suffering from constant frontal headache; she was very feverish, had lost appetite, and had a diarrhœa. I found her in bed, with a temperature of 103°, very quick, compressible pulse, tongue dry, and a number of rose-colored spots over the abdomen and chest. The case was running the ordinary course of typhoid fever, when, on May 5th, the child was taken with a sudden, sharp pain in the right iliac region; my visit found the child suffering agonizing pain in the abdomen, which was tense and swollen; in the right iliac region could be felt a lump the size of an egg; under appropriate treatment the acute pain somewhat subsided. On May 8th, my attention was called to the navel, which had become red, inflamed, and pouting; on touch, a feeling of fluctuation was imparted to the finger. May 10th, the child passed from the bowels a large quantity of pus; the angry appearance of the navel disappeared, all acute symptoms seemed abated. On my visit of May 12th I found the navel again inflamed, with positive indications of pus underneath; the following day it broke, discharging about a cupful of pus. I now suggested a consultation in regard to the advisability of an operation. It was declined. Same condition continued up to the first of June; the child by this time had become greatly emaciated, constant discharge of pus from the navel, and symptoms of septic poison were commencing to show themselves. At last, on June 12th, consent was given to an operation. June 13th, Drs. Allis, F. Elder, and C. Reed were present. The patient was etherized by Dr. Reed; after a close examination, and taking the weakened condition of the child into consideration, and also that the abscess cavity having made an opening at the navel, it was decided that, instead of opening the abdominal cavity, a counter-opening in the left iliac region be made, and a drainage-tube, extending from the navel to it, be introduced, and the abscess cavity washed out. I washed out the abscess cavity through the tube with a two-quart solution of 1 to 4000 biniodide of mercury; the abdomen was then covered

first with biniodide gauze, over which was laid a layer of the biniodide wool, all held in position by a bandage that had been washed in a 1 to 4000 solution of the biniodide of mercury. The abscess cavity was ordered to be washed out morning and night with a 1 to 8000 solution of the biniodide; the child rallied well from the effects of the ether. While washing out the cavity, on May 17th, a piece of straw came through the drainage-tube. May 22d, discharge of feces through the lower end of the tube, which occurred two days in succession; for the following ten days, when the child partook of food, more especially if this was an egg, within a half hour some of it partially digested would appear at the end of the upper part of the tube; if the discharge occurred later than a half hour, it would appear at the lower end of the tube: this clearly demonstrated a fecal fistula in connection with the abscess cavity. Gradually all discharges ceased, and the tube was taken out July 23, 1887; a week later both openings were closed, but it was several months before the child could resume her ordinary diet; apples would invariably bring on severe colic.

None of us at the time of the operation went further than to "hope" that the little patient would get well. The case demonstrates well the antiseptic properties of the biniodide. It was an extremely warm month, and, with the exception of the two or three days on which the feces passed down through the tube, the odor of the discharges was held in abeyance.

Double Laceration of the Cervix.—Mrs. F. had a large, double laceration of the cervix following a natural labor. I first saw the case in May, 1885, and advised operation. Operated October 5, 1885. Extensive denudation had to be made; fourteen silver stitches were necessary; hot water was used to cleanse the parts during the operation. On the second day a very offensive bloody discharge occurred. The vagina was washed out with a hot 1 to 4000 solution of the biniodide of mercury three times a day; at the first injection all odor disappeared, and did not return throughout the rest of the treatment; the stitches were taken out on the tenth day, with perfect union.

Abscess of Right Foot.—In February, 1887, I was called to see Master McG. About a week previous a heavy box fell on his foot; painful at the time, but not painful enough for him to give up his work, he continued to work up to February 10, 1887; on the previous evening his foot became swollen and painful; under poultices the inflammation centred, and on February 20th the abscess broke. The opening was stubborn to heal; offensive pus was discharged; every day I injected the cavity with a 1 to 2000 solution of the bichloride of mercury and packed; this treatment was kept up for ten days without any change; the bichloride was then changed to a 1 to 4000 solution of the biniodide of mercury, the discharges were made pure, and in the course of another ten days the opening closed, but the foot remained tender for several weeks.

Abscess Extending from the Right Axilla.—W. S., aged thirty, barber, of scrofulous habit, somewhat dissipated, having a wart on the right middle finger, picked it with his finger-nails; the result was an acute inflammation of the entire arm. I saw the case July 16, 1888; under cooling applications, the inflammation soon abated. About July 21, 1888, the right side, extending from the axilla down to midway between the last rib and the crest of the ilium became intensely inflamed; the pain was excruciating, and large doses of sulphate of morphia gave only momentary relief; large flaxseed poultices liberally sprinkled with laudanum were applied. On the 24th I detected fluctuation at the lower border, made an exploratory incision, and obtained half a cupful of fetid pus and broken down blood; this gave slight relief. On the 26th the pain returned tenfold; the same evening, the patient having been etherized by Dr. S. Solis-Cohen, I enlarged the previously made incision to three inches, and about half a pint of extremely fetid pus was discharged; the finger was then introduced, and two encysted pus sacs, situated at the edge of the scapula, were ruptured, and another half pint of pus was discharged; the cavity was then washed out with a 1 to 4000 solution of the biniodide of mercury, a drainage tube introduced, flaxseed poultice applied, and over all a layer of biniodide wool.

Next day I found the patient had had a good night's rest; I removed the poultice; cavity to be washed out three times a day with the biniodide; drainage tube taken out on the fourth day, and within a week the patient was discharged well. It is hardly necessary to state that good nourishment, iron, and quinine were ordered. After using the biniodide no odor was perceptible in the discharges.

Three Cases of Carbuncle.—April 23, 1887, I was asked to see Mrs. P., aged seventy-two, and found her suffering with a carbuncle on the back of the neck, six inches long and four inches wide. It was

riddled with a number of suppurating points; on the previous day the patient had been given up by her medical attendant as incurable. On Sunday, April 24, 1887, after the patient had been etherized, the wound, instruments, and sponges were made antiseptic by being washed with a 1 to 4000 solution of the biniodide, after which a crucial incision was made and all the hardened tissue dissected out, down to healthy tissue, thoroughly washed out with the biniodide, and a flaxseed meal and charcoal poultice applied; the sore to be well washed three times a day with the biniodide, when a fresh poultice was applied. Internal treatment, iron, quinine, and full diet. In twenty days the patient was discharged well. The disagreeable odor in this case was not entirely dissipated, but was held under control.

Case II.—Mr. B., coal merchant, aged forty. Carbuncle in right shoulder, size of an egg, hard, indurated, extremely painful to the touch, and a point of suppuration at the centre; the case was seen April 7, 1888. The next day, after the patient had been etherized, I made a deep crucial incision, and dissected out all the hard indurated tissue; the same treatment was used as in Case I. No odor connected with the discharges. Patient discharged, cured, in two weeks.

On October 20, 1888, I was again asked to see the above patient. I found him suffering from an attack of herpes of the back of the neck, which was, in a few days, followed by a number of abscesses, two of them resembling small carbuncles. A charcoal poultice was applied, and in three days all the abscesses were opened, but during the following week there seemed to be no change for the better. I then ordered a piece of linen to be saturated with a 1 to 4000 solution of the biniodide and applied to the surface, and over this a flaxseed-charcoal poultice; within forty-eight hours, the angry appearance of the abscesses and skin abated, and in four to five days more, all inflammation had disappeared, when the patient was discharged.

Case III.—J. E., aged sixty-nine, was taken sick about three weeks previous to my seeing him. It first commenced with a painful tumor on the neck. When I saw the patient (July 19, 1888), the entire surface from the superior curved line of the occipital bone down to the seventh cervical vertebra and from ear to ear was one immense suppurating surface, covered with a thick yellowish green membrane. The discharges were highly offensive. Pulse quick and compressible; slightly delirious; tongue covered with a thick, black, highly offensive membrane. Ordered a piece of linen to be saturated with a 1 to 4000 solution of the biniodide and applied over the surface, and over this a charcoal-flaxseed poultice every three hours. The odor was held in abeyance. This treatment was continued for about ten days, when the surface became clear of all adventitious membrane. Poultice was continued; carbolic acid was ordered in place of the biniodide. Patient discharged, cured, September 20, 1888.

Dr. S. Solis-Cohen saw the case for me in August, and we concurred in one prognosis, which was death; but we were more than agreeably surprised.

Biniodide of Mercury Wool as an Application over the Chest in Pulmonary Troubles.—When, in the winter of 1886, I first ordered the chest of a child suffering with catarrhal pneumonia to be enveloped in a layer of the biniodide of mercury wool, it was simply to overcome the disagreeable matting of the cotton. The child, previously to its use was very restless, and seemed to suffer pain. On the following visit I found that the little patient had had its first quiet sleep since the commencement of its sickness; since then I have almost entirely discarded the use of cotton. The results in a number of cases lead me to believe that there must be something more than the warmth of the wool. Can it be that the heat of the body disengages the biniodide, and as the consequent result, the patient is constantly surrounded by an antiseptic atmosphere?

In a case operated on for cancerous constriction of the bowel, by Dr. Charles B. Penrose, the patient, about the fourth week, was seized with a sharp pain in the right side below the nipple; counter-irritants did not relieve her; on auscultation, crepitant rales were easily detected in the lower right portion of the lung, under the point where the pain was complained of; the side was enveloped in the biniodide wool, and within twelve hours the pain had entirely disappeared. In the neuralgic pains always present in a case of phthisis, I have found the wool invariably to diminish, if not entirely dissipate the pains, and the expectoration seems easier and in smaller quantities.

My attention was called to the following by my office-pupil, J. N. England: "Biniodide of Mercury Pulverization for Tuberculosis" (*American Journal of Pharmacy*, October, 1888). Miquel and Rueff's for-

mula is given by the *Arch. de Phar.*, September 5, 1888, as follows: Biniodide of mercury and iodide of potassium, of each 1 gramme; distilled water, 1000 grammes. The solution is stable. At the beginning 10 c.cm. are sprayed once daily; to be increased to 25 c.cm. twice daily. The larger portion of the liquid should be inspired. It reaches the lungs, says the author, but salivation does not follow, even after months of treatment. The sputa changes in character and diminishes in quantity; the number of microbes is lessened, but these organisms rarely disappear completely. The cough increases at first, and afterward subsides.

If my theory of the disengagement, by heat, of the biniodide from the wool be correct, its action will readily be explained by the above experiments of Miquel and Rueff.

Disinfectant of Typhoid Fever Stools.—For the past two years I have used the pellets of the biniodide dissolved in the alvine discharges of typhoid fever, and the results have always been satisfactory.

In the spring of 1886 I treated an extremely bad case of typhoid fever; the patient was broken down from dissipation, having had, about two weeks prior to his illness, an attack of delirium tremens; the alvine discharges numbered from twenty to thirty a day, and were highly offensive; chloride of lime, and different forms of chloride and sulphate of iron were used without any diminution of the sickening odor. I then ordered two (1 to 4000) pellets of the biniodide of mercury to be dissolved in a half pint of water and placed in the bed-pan, to be renewed every time the pan had been used by the patient; the odor was completely dissipated, and kept so.

In another case the bichloride of mercury pellets were used without success; the biniodide pellets gave the desired result. In a case of labor which, at the end of the lying-in, terminated in an attack of typhoid fever, the nurse used the biniodide pellets on her own account in the bed-pan, there was no disagreeable odor throughout the course of the disease.

The description of the action of new medicinal preparations or new properties to an old medicine necessitates tedious histories of cases; this must be my excuse for dragging through such dry details.

It is not my intention to present to you the biniodide of mercury as the one and only infallible antiseptic; I simply present my results, and have tried to give impartial histories, without exaggeration, simply as they have occurred. But the action and results of the biniodide of mercury fully strengthen my belief in its stronger antiseptic value and non-irritating properties over the bichloride.

After some remarks by Dr. Woodbury, Dr. Bernardy closed the discussion. He said: From the start I objected to the shape of the pellets, thinking that they looked too much like candy, and I think that there will soon be a change, so that this danger will be avoided. The pellets of bichloride look very much like chlorate of potassium lozenges, with the exception that the word "poison" is stamped on them.

In regard to this being a double salt. This was the first thing that struck my attention. When I first used this preparation, in 1884, I dissolved the biniodide in alcohol. This was found to be inconvenient, and through the kindness of Mr. Hayes, who allowed me the use of his laboratory, his assistant and I worked up this subject. We added iodide of potassium, and then found that the slightest moisture imparted to one pellet was enough to destroy the entire bottleful. We then decided to add the muriate of ammonium, which prevents this chemical reaction until the pellet is thrown into water. The pellet goes in as the biniodide of mercury, and the iodide dissolves it, but before the change takes place it has been used upon the patient.

In regard to my use of this preparation. I have studied it faithfully, and have tried to look upon the cases in an unbiassed way, and to give a fair history of them. I have sometimes first used the bichloride, and it has not fulfilled the indications as the biniodide has done.

—The *Medical Press and Circular*, Feb. 6, states that an action was recently brought against M. Poncet, Surgeon to the Val de Grâce Military Hospital, for $10,000 damages for having performed the operation of breaking down the adhesions in an anchylosed knee, the result of which did not fulfil the expectations of the patient. The Tribunal declined to enter into the technical question of the propriety of the operation, and restricted their consideration to proofs of negligence or manifest incapacity. A verdict was arrived at exonerating the defendant on the ground that although unsuccessful, the operation had been performed after due deliberation and with every necessary attention.

Reports of Clinics.

BELLEVUE HOSPITAL, NEW YORK.

MEDICAL CLINIC—PROF. A. A. SMITH.

Broncho-Pneumonia.

Prof. Smith presented a patient to illustrate an important fact which he had just previously laid stress upon in his lectures; namely, the great significance of the combination of the three physical signs—broncho-vesicular breathing, increased vocal resonance, and slight dulness. The patient, a man 36 years old, had been an inmate of the Hospital for many years, on and off, and always had a simple bronchitis. Dr. Smith himself had examined him many times before. A short time ago he was again admitted with the same trouble, the physical examination of his chest showing nothing but a general bronchitis. Three days ago, however, he suddenly had a chill, his temperature went up to 105° F., and his cough and dyspnœa increased. He complained of no pain. His fever continued, controlled to some extent with five-grain doses of antifebrin, and to-day is 102° F. The examination of his urine is negative.

The question arises, is his present condition the result of his bronchitis alone, or of something else? Physical examination of his lungs shows the presence of dry and moist rales all over, and posteriorly at the right apex a very localized spot presenting dulness, broncho-vesicular breathing, and increased vocal fremitus. This small area of consolidation did not exist before the occurrence of the chill three days ago, and it is so limited in extent that the most careful examination is necessary to determine it. It is a broncho-pneumonia; and what is its significance? There is no heart disease, and examination of the abdomen is negative. It is probable, therefore, that the inflammation is tubercular. The sputum has not yet been searched for the tubercle bacillus: but even if it is not found the diagnosis is not rendered clearer. A good prognostic sign and one against a tubercular process is the non-involvement of the pleura. And it is not altogether unlikely that the pneumonia may clear up and the patient recover. But if this does not occur in two weeks time we may quite positively diagnosticate phthisis.

These cases often occur in practice and are sometimes not so clearly defined as this one. With the bronchitis there may be no increase of cough or fever, and only the most careful examination will reveal the presence of consolidation. Moreover, the physical signs of this condition may not be very pronounced.

Lobar Pneumonia; Pericarditis.

The second patient was a man, 25 years old. Six days ago he was attacked with chill, fever, pain in the left side, cough, etc., and on admission to the Hospital he presented all the signs of lobar pneumonia. During the night he had mild, muttering delirium. After three days, his delirium suddenly became violent; he jumped from bed and rushed to the window and would have thrown himself out if he had not been promptly restrained and by force carried back to his bed. His temperature increased, and cyanosis developed. With this history pericarditis was at once suspected to have developed, and examination revealed a marked pericardial friction sound, which had not previously existed.

This sudden delirium in pneumonia very often signifies the access of pericarditis. To be sure the delirium may be due to other causes, as alcoholism or renal disease, or occur independent of any complication; but the frequency of its connection with pericarditis is more than a coincidence.

The patient has been taking half an ounce of brandy every half hour, day and night. His delirium is much improved and his cyanosis diminished. His pulse is now 140, compressible, but not very feeble. The rules laid down in a previous lecture relative to the use of alcohol are: consideration whether the illness be of long or short duration; the presence of a dry brown tongue; a feeble pulse of 120 or over, and increased first sound of the heart; and cyanosis. In this case we cannot be guided by the pulse altogether, and by the heart not at all. We notice the tongue to be dry and brown and fissured (what is called semi-typhoid), and we have the cyanosis—sufficient indications for stimulants. It is now the sixth day of the disease, and in twenty-four hours there will be, probably, a fall of temperature, for Dr. Smith believes the prognosis to be good.

In these cases of pneumonia the diagnosis is easy. There is almost always a chill (in 59 cases recently observed there was no chill in 14); and it is usually well marked, as in this case, lasting one-half hour. The pain in the side, the cough and finally the

physical signs, are usually prominent and characteristic.

With reference to treatment: if there be much cough, dyspnœa or nervous symptoms, give opium and control the nerves. If complications arise, give more opium and add alcohol. Dr. Smith believes opium the most valuable drug in pneumonia. It does not treat the pneumonia, but the patient. Give sufficient to relieve the pain and just moisten the skin. It certainly renders the patient comfortable.

Phthisis.

The third patient was a woman, 37 years old, the mother of eleven children. Six years ago the patient had pneumonia of the right lung, and at that time was in bed six weeks. She has had no sickness since. For some weeks previous to three weeks ago she had had slight cough but no fever and no physical signs of consolidation of the lung, so we are told. Three weeks ago she began to expectorate blood and complain of moderate pain in the right side, high up.

To-day, physical examination shows, at the right apex, retraction and diminished movement, dulness, to three or four inches below the clavicle, bronchial breathing, and rude voice. The patient has laryngitis, and her voice and vocal fremitus are not therefore reliable. The patient has had several slight hæmoptyses since the first attack; sometimes the blood is bright and frothy, sometimes it is dark and clotted. It is probable that this condition of the lungs has existed longer than three weeks.

Hæmoptysis does not make the prognosis in this case more favorable or more unfavorable. The late Dr. Flint has said that life is longer in those patients who had this symptom.

Dr. Smith would prefer, were he the subject of phthisis, to have a moderate hæmoptysis occasionally, and would then consider his chances better; for this symptom seems to occur in the long-continued cases. There are to-day, among many such examples, several practising physicians in New York, old men, who had hæmoptysis thirty and forty years ago.

The treatment in this case should be toward improving the general health. Astringents do no good.

Typhoid Fever.

The fourth patient was a man 20 years old, a machinist. He had been nine months in the United States. He is not intemperate. He was well up to five days ago; he then complained of chilly sensations, cough, headache, and feeling "light and dizzy." There has been no nose-bleed and no pain. The bowels move once a day; are free, but not watery, and are of natural appearance.

The temperature is 103°; pulse, 110. The patient is pale and dull of apprehension. There are slight diffuse bronchitis; enlarged and tender spleen and liver; gurgling and tenderness in both illiac fossæ.

The diagnosis rests between malarial and typhoid fevers, and quinine, in sufficient doses, should be administered to settle this point. If after three days, the temperature is not controlled, the case is probably one of typhoid fever.

New York Correspondence.

Treatment of Club-foot at the University Medical College.—A good caustic for Cancer.—Clinics of Drs. Bull, Thomson, and Winters.

New York, Feb. 16, 1889.

Two years ago Dr. N. M. Schaffer was succeeded as lecturer in orthopædic surgery in the University Medical College by Dr. A. M. Phelps. A more radical change would be hard to conceive. Prof. Schaffer is a disciple of braces and similar instrumental appliances, rather than of the knife; while Prof. Phelps is directly the opposite. The latter has now operated on nearly one hundred cases of club-foot without a failure and without a death, his highest temperature being 103°. He says he has never seen the case that operation will not cure. His good results are explained by his perfect knowledge of the subject, his skill and fearlessness in operating, and by the strictness of his antisepsis. He lays down the following rules of treatment: If a foot can be reduced by a reasonable amount of force in a reasonable time, do not operate; if not, the foot should be treated first by subcutaneous tenotomy; if this fails make a large open incision and cut everything; should this fail because of deformity of the bone, perform linear osteotomy of the neck of the astragulus; if the deformity is still unreducible, cut out a V shaped piece of bone; and lastly, if it remains then unreducible, cut off the foot. He considers it better to have a shoe stuffed with cotton and going naturally forward than one filled with a deformed foot and going backward like a crab. Prof. Phelps is also lecturer on orthopædic surgery in the Postgraduate School.

In cancers unamenable to treatment by the knife, Prof. Stephen Smith uses the following caustic: Heat sulphate of zinc till the water of crystalization is driven off and the sulphate falls into a powder. Add pure sulphuric acid to any desired consistency, that of mortar being preferable. This paste when applied produces a granulating surface that heals with surprising rapidity.

At the clinic of Prof. W. T. Bull, in New York Hospital recently, ovariotomy was performed for pyosalpinx. The tubes and ovaries were found bound down behind the uterus. They were torn loose without rupture and without great bleeding, and then, after the usual ligatures had been applied, they were removed. The Doctor feared hemorrhage and left in the wound a large glass tube, to which the nurse was instructed to apply suction with a syringe at intervals. Bleeding would thus be detected and free drainage at the same time obtained. He next operated on a case of ventral hernia. The patient was forty years of age and a janitress by occupation, compelled to do a great deal of walking up and down stairs. The hernia when tense was as large as a hen's egg, and gave considerable pain. Though the hernia was of long standing, no truss had ever been worn for it. It was easily reduced. Dr. Bull said he had not had a large experience in this variety of hernia but he believed that the results of operation were not brilliant, especially when the walls of the abdomen were weak and flabby. In this case they were strong and muscular and by excision of the sac and careful approximation of the edges of the muscle he hoped for a good result. A number of large vessels were found in the sac, but no serious trouble resulted.

At the clinic of Prof. W. H. Thomson, a policeman presented himself who apparently was the picture of health. His pulse, however, was irregular. He complained of headache and disordered secretions, sometimes diarrhœa at other times constipation. His worst symptom, however, and the one for which he came for relief, was insomnia. He could find nothing that helped him. Dr. Thomson said it was due to disordered circulation and fermentation in the intestine. He ordered:

℞ Tr. strophanthi . . . . . gtt iv
Spir. ammoniæ aromat. . . . . f℥j

M. Sig. Take on retiring. To be repeated in four hours if the first dose does not put him to sleep.

After two weeks ten to fifteen grains of chloral hydrate with gentian, whiskey and iron may be substituted. If strophanthus fails to regulate the heart, digitalis may be tried. For the intestinal fermentation salicylate of soda and salol were given. The Doctor said insomnia may be the result of habit, in which case it should be treated with chloral hydrate until the habit is broken. Another cause is worry or mental strain. This variety is most dangerous and may lead to epilepsy or insanity. In this case give:

℞ Dilute hydrocyanic acid . . . gtt xvj
Majendies sol. morphine . . . f℥j
Chloral . . . . . ℥jss
Syrup of ginger . . . . . f℥j
Camphor water . . . . . ad f℥vj

M. Sig. Dose, for ordinary case, tablespoonful; for severe case, two tablespoonfuls.

This prescription is also good for the sleeplessness of fatigue.

Prof. J. E. Winters, in a course of clinics and lectures on diphtheria in children, at the University Medical College, has laid down the following rules for its treatment. It is the treatment followed in his private practice and in the University and De Milt Dispensaries, and he vouches for its results. Exhaustion and laryngeal complications are the chief causes of death, and are the things to combat. To prevent the former put the patient in bed and keep him there, no matter how mild the case may be. The latter cause of death is always brought on by exposure, and hence the bed should be placed out of reach of all draughts and the patient's neck should be kept warm. If flaxseed poultices are used they must be kept hot and changed every hour at least. A good method is to apply fat pork or bacon well sprinkled with pepper, both to the neck and up the sides of the face. Use heat by the inhalation of steam. As it is exhausting do not use it constantly but for ten or fifteen minutes, several times daily. Sulphurous acid, obtained easily by burning a piece of sulphur in the room, aids in the exfoliation of the membrane, reduces congestion and promotes the health of the sore. Local treatment: When the diphtheritic inflammation is under direct observation, as on the tonsils, local treatment is of little avail, and, as it causes struggling and consequent exhaustion, is contraindicated. In nasal diphtheria, however, the local treatment is most important and can be had without exhaustion. Place the patient on the edge of the bed and use a Davidson syringe until a passage is obtained through the nostrils. The saturated solution of

boracic acid is the best application and, if there is putrefaction, alcohol can be added (f ʒ ss to Oj). General treatment: Begin with calomel (gr. ij into ten powders, one every hour) as it stimulates all the secretions. Iron in full doses is indicated. Ten drops of the tincture of the chloride can be given and, if borne, doubled after twenty-four hours. If there is sepsis even (f ʒ j) doses can be given. If quinine does not irritate, it should be given in tonic doses (to a child two or three years old, gr. j t. i. d.). Give alcohol only when the pulse indicates its necessity, beginning with gtt. x. If the disease is extending downward, in addition to the above burn tar in the room. Its *modus operandi* is unknown, but it relieves the symptoms and also spoils all clothing with which it comes in contact. Carry the nutrition of the patient to the highest pitch with milk and beef tea.

PERISCOPE.

On Gas-Cysts of the Vagina.

Professor Obrzut (pronounced "Objüt"—a Polish name), of Prag, Bohemia, says (*Wiadomosci Lekarskie*, Aug., No. 2, 1888) that Dr. Jacobs, of Bruxelles, working under his guidance, has succeeded in elucidating the pathogenesis of a rare and curious affection of the vagina. This consists in the development of multiple small-sized cysts with gaseous contents, described by Professors Chiari and Breisky under the name of "emphysematous vaginitis." While both of the authors just named, as well as Dr. Piering, believe that the disease represents primarily a lesion of the vaginal lymphatic apparatus, Drs. Obrzut's and Jacobs's researches have shown that the cysts originate solely in the vaginal blood-vessels, the lymphatics remaining wholly intact. According to the latter authors, the first stage of the pathological process seems to consist in œdematous swelling affecting fairly circumscribed isolated areas over the vascular wall; the second stage is a progressive, correspondingly limited or localized obliteration of the vascular lumen; while a third stage consists in a more or less considerable gradual dilatation of the vessel above its stenosed portion. Those dilated departments of the vascular tube in the course of time are transformed into cystiform structures, while their bloody contents undergo disintegration which, amongst other products, yields odorless and colorless gases. As to the microbes described by Eisenholz, they could not be discovered in the cysts by any method of examination.

Friedreich's Disease.

At the meeting of the Medical Society of London, Jan. 28, Dr. Harrington Sainsbury brought forward two cases of Friedreich's disease. The first occurred in a compositor, twenty-three years old, single, who was treated at the age of fourteen for St. Vitus' dance. The ataxia, the patient says, developed a year or two later. He had an attack of abdominal symptoms of obstructive character at the age of nineteen, and since then the ataxia had increased. The incöordination presented the characters usual in locomotor ataxia, affecting the arms and legs, but being most marked in the latter. There appeared to be some muscular weakness, the head was occasionally unsteady, the speech was thick, and the eyes showed slight lateral movements when looking upward. The pupils were equal, contracting to light and accommodation; the discs were normal. Sensations as of "pins and needles" were felt occasionally in the hands and feet, and cramps sometimes in the legs; the patient felt the ground under him. On testing the sensation, it was found slightly dulled in the feet and legs; there was no delay in perception. Muscular sense for posture and estimation of weight was fairly precise; the superficial reflexes and knee-jerks were absent, and there had been no urinary trouble. The facial expression was blank.

The second patient was a brother of the first, two years younger, presenting a similar condition, but the thickness of speech and blankness of expression were more marked. There was a third brother in the family affected in a like manner. The lesion was identical in position with that of tabes, but there was absence of pain and of cramps.

Dr. Ormerod quoted several cases which had at first, and often for considerable periods, been mistaken for St. Vitus' dance. Looking at the constant unsteady movement in these cases, it was very hard to say that chorea was altogether absent. Dr. Sainsbury's case became worse after an acute abdominal attack; he had noticed a similar tendency to development of the affection after acute diseases—*e. g.*, scarlet and typhoid fevers.

Dr. Sainsbury, replying to a question from Dr. Beevor, said that the father was a drunkard, but there was no family history of neurosis.—*Lancet*, Feb. 2, 1889.

Bacteriology and Antisepsis of the Conjunctival Sac.

In the St. Petersburg weekly *Vratch*, Nos. 43 and 45, 1888, p. 879, Dr. Joseph S. Felser, of Kazan, describes his instructive bacterioscopical researches, undertaken for the purpose of studying mycotic life within the human conjunctival sac, as well as with the view to discover the best method of aseptic and antiseptic management of the conjunctiva in cases of ophthalmic disease and operations. The main outcome may be condensed thus: 1. The conjunctival sac in man always, both in health and disease, contains large numbers of microbes of different species. 2. This mycotic "store" is incessantly kept supplemented and refreshed by a free supply from enormous masses of microörganisms invariably present in the surrounding air. 3. The numerical strength of the conjunctival microbes is directly proportionate to that of the air bacteria. 4. Of pathogenic microbes, the predominating species are the *staphylococcus albus*, *citreus*, *aureus*, and *diplococcus*, the first two forms prevailing also under absolutely healthy conditions. 5. In conjunctival catarrh, the *staphylococcus pyogenes aureus* occurs most constantly and in greatest numbers. 6. In inflammation of the lachrymal sac the diplococcus is invariably present, and that usually in a "pure culture." 7. Panophthalmitis developing after extractions of cataract is caused by the *staphylococcus pyogenes aureus* present in the conjunctival sac. 8. Of antiseptic ophthalmic means in vogue, corrosive sublimate (in the form of irrigations with a solution of 1 to 6,000) is exceedingly weak and untrustworthy in its action, while boracic acid (in the form of irrigations with a three per cent. solution) and iodoform (in powder) are ineffective altogether—they are powerless to destroy the vitality of the microbes or even to arrest their proliferation. 9. The best aseptic and antiseptic means yet known for use in eye practice, is, undoubtedly, trichloride of iodine (ICl_3) recently introduced into surgical practice by Drs. O. Riedel and C. Langenbuch. 10. While being wholly innocuous and void of any irritant properties, the trichloride is most effective in the destruction of microörganisms of any species. 11. In suppurative affections of the conjunctiva, the irrigation with a weak solution (1 to 6,000), repeated three, four, or five times a day, never fails to bring about rapid and striking amelioration. Even after the first three or four sittings, the purulent discharge becomes trifling or often ceases altogether, congestion lessens, and all unpleasant subjective sensations disappear without leaving any trace.

A New Deodorant.

Bromine has for a long time been recognized as being valuable in the treatment of gangrene and foul-smelling ulcers, but until recently its merits as an effectual and cheap deodorant have not been appreciated. It was brought into prominence a few months ago by Mr. Martin, the chemist of the Health Department of New York City, who suggested its use upon the earth thrown up in laying the electric subways. As it is a by-product obtained in the manufacture of salt and is not used extensively in the arts, it is sold at a very reasonable price—about seventy cents per pound. It has the property of precipitating the hydrocarbons of illuminating gas, and thus can be used to deodorize the earth exposed in excavations in the vicinity of gas-mains. More valuable than this is its effect upon decomposing organic bodies, which it renders completely inoffensive. This property renders it especially valuable for use in stables, privy-vaults, urinals, cess-pools, or in any place which may contain foul-smelling organic matters. It is soluble in about thirty-three parts of water, but a solution of this strength is not advisable, as there is a constant escape from it of the vapor of bromine, which is very irritating to the eyes and air-passages, and which may even attack wood and metals. For ordinary purposes it is used in solutions containing one part by weight to about eight hundred of water. In this strength it may be used freely without its affecting anything which it may touch. A few gallons used daily will remove all ammoniacal odors from stables, or a few quarts will thoroughly deodorize the entire plumbing system of an ordinary house. It also might be used with advantage upon ordinary house garbage, which usually becomes offensive so speedily in warm weather. There would appear to be scarcely any limit to its usefulness in this branch of sanitary science, and it will, as soon as its merits are better known, undoubtedly be adopted universally as a substitute for the deodorants now in use, which usually act by substituting one unpleasant odor for another. The only drawback in its use lies in the fact that the undiluted bromine is strongly corrosive, and, if it touches the skin, causes a painful burn. Where it is used in large quantities

this can be obviated by opening the bottle or, what is simpler, breaking it under water. As its use becomes more extended it will undoubtedly be put up in pearls or tubes containing only as much as would be needed at one time in the average household.—*N. Y. Med. Journal*, Feb. 2, 1889.

Compound Gonorrhœal Infection.

Bumm, in prosecuting his studies upon the gonococcus, has discovered that infection by two distinct varieties of microorganisms can take place, the first preparing the way for the entry and development of the second.

Thus pyogenic microbes may enter one of Cowper's glands after the gonococcus has destroyed its glandular tissue and caused cystic degeneration, and produce suppuration. The mucous membrane of the bladder or urethral follicles may be affected by the staphylococcus in like manner, and the pelvic connective tissue may be invaded. Tubercular disease of the epididymis and tuberculosis of the Fallopian tubes have been known to follow closely upon a gonorrhœa, and are explained in the same way. In gonorrhœal rheumatism the micrococci found in the fluid of the joints are pyogenic, but why they should make their way to the articulations, and the gonococci not do so, is a question still unexplained.

Another source of error is the nodular lymphangitis of blennorrhagia. Small olive-formed tumors are produced along the course of the lymphatics as large as a cherry-stone or a small nut, and are firm, hard, and resistant. They arise insidiously upon the prepuce, but their seat of predilection is the glando-preputial groove, and when hidden by a phimosis they are especially liable to cause an erroneous diagnosis. The diagnosis can, however, be made with almost certainty by the adenopathy, when multiple indolent and long-lasting ganglionic enlargements are present.

These lymphatic nodules are essentially prone to resolution, but when they ulcerate, as they sometimes do, typical indurations characteristic of chancre are presented. Here the only element of diagnosis is found in the evolution of the disease. The indurated chancre never begins as a nodular lesion which opens like an abscess. The diagnosis of chancre should never be made from the objective signs alone. The ecthyma of scabies may easily lead into error, resembling, when covered with a crust, the *chancre croûteux;* or when excoriated, red, and ulcerating, the ordinary chancre. The glands are often implicated in scabies, and the error of overlooking a chancre in a patient with lesions of scabies upon the genitals must be borne in mind. Treatment directed against the itch will soon make the diagnosis clear.—*Journal of Cutaneous and Genito-Urinary Diseases*, Feb., 1889.

Absorption of the Tissues of the Mouth from Pressure.

The absorption which occasionally takes place from constant pressure upon the tissues of the mouth was well exemplified by two cases brought forward at the Odontological Society of London recently by Mr. Hern and Mr. E. Lloyd Williams respectively. In the first case, the patient had been wearing a set of artificial teeth, the upper and lower of which were attached by means of springs. She had not removed these teeth from her mouth for several years, and, as a result, the lower had become buried in the floor of the mouth; it was also so twisted round as nearly to sever the anterior pillar of the fauces. There was found to be complete anæsthesia of the right half of the tongue and corresponding portion of the floor of the mouth, also complete loss of the sense of taste on that side. There was no pressure on the inferior dental nerve, as sensibility was present in the skin over the chin. The plate was removed with considerable difficulty, and caused much hemorrhage. Some weeks later Mr. Hern observed a whitish cord passing across the gap in the anterior pillar of the fauces; this proved to be the gustatory nerve, and on pinching it with tweezers a tingling sensation was felt in the tip of the tongue. Nine months later sensation had partly returned in the tongue.

Mr. Lloyd Williams showed a man who had extracted two loose molars for himself, the sockets of which probably communicated with the antrum. The patient, being annoyed by the cavity, plugged it with gutta percha, gradually increasing the size until a plug was used measuring more than an inch in diameter. The hole, however, was much larger than this, as the patient was in the habit of encircling the gutta percha with a piece of lettuce leaf. The walls of the antrum presented in places foul ulcerated spots, which, however, speedily disappeared when an obturator was placed in the mouth and antiseptic injections were used.—*Lancet*, Jan. 19, 1889.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - - -	**1.00**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

EXTIRPATION OF TUMORS OF THE BLADDER.

The general adoption of the operation of supra-pubic cystotomy in Europe has led to much more frequent attempts to remove tumors of the bladder than were made a few years ago, when only the difficult and uncertain route through the perineum was open to surgeons. At present no tumor is permitted to make serious advances or to do serious harm to a patient under the observation of a surgeon without an effort to remove it; and nowhere is this more true than in Paris, where the supra-pubic operation is practised almost to the exclusion of other methods.

An illustration of the scope of this operation is furnished by a case described in a recent lecture by Dr. Bazy, at the Hôpital Beaujon, which is reported in the *Bulletin Médical*, January 16, 1889. In this case, after the usual history of a papilloma of the bladder, the patient came under the care of Dr. Bazy, who opened the bladder from above the pubes, and removed a tumor about two and one-half inches in diameter, situated on the right side of the bladder and encroaching a little upon the *bas-fond*. After describing the operation—in which he unwittingly cut off the lower end of the right ureter—Dr. Bazy states his opinion that excision of tumor of the bladder is preferable to enucleation, or scraping, or cauterization. Total ablation is, he thinks, the only way of dealing with these new growths, and that this should be practised as early as possible and made as thorough as possible. The line of excision, he says, should pass through the healthy mucous membrane, and it may even include the opening of one or both ureters, if necessary. In case this is necessary, he thinks the stump of the ureter should be attached to an opening in the bladder-wall, made to receive it. Of course, in such an operation the wound in the bladder and abdominal wall should not be entirely closed, and a suitable drainage-tube should be left in the bladder.

These views are radical, but we believe entirely sound. Tumors of the bladder are dangerous, not only on account of their local and immediate effects, but also on account of their influence upon the kidneys and their proneness to recurrence. It is rational to remove them—as Dr. Bazy advises—as early and as thoroughly as possible, and we think he makes a good point when he prefers excision to the easier methods of scraping or cauterization.

EXPULSION OF FOREIGN BODIES FROM THE ALIMENTARY CANAL.

It is now well understood that very many foreign bodies which have been swallowed will pass through the alimentary canal without giving rise to disturbance, if they are left to nature, and especially if a full vegetable diet is recommended and the use of purgatives is avoided. But it remained for Dr. Cameron, of Glasgow, to propose, for the management of cases of this sort, a formal method which is called the "potato-cure." It consists simply in getting the patient to eat large quantities of potato, which are expected to surround the foreign body and conduct it innocently through the intestines. This plan has worked admirably in a number of cases, and many foreign bodies, both sharp and of irregular form, have been successfully expelled from the alimentary canal under its working.

The subject was brought before the Royal-Imperial Society of Physicians of Vienna, January 11, 1889, and Dr. Cameron's method was warmly endorsed by several distinguished men who had tried it. The general opinion was that it might often obviate the necessity for laparotomy; and a case was reported by Dr. Hochenegg, in which by this means a foreign body had been removed in nine days precisely similar to one which had been removed by laparotomy by Prof. Albert four or five years before.

Such a showing certainly justifies calling attention to this method, although—as stated above—its underlying principles are well enough understood by most medical men.

DEATH CAUSED BY COCAINE-HABIT.

It is reported from Cincinnati that a physician of that city died recently from the effects of cocaine which he had formed the habit of taking frequently. It is said that he began experimenting with the drug a few years ago, and that he soon became a hopeless victim to its influence.

This is a sad story, and one which has a moral. Every now and then it happens that a physician becomes engaged in the toils of alcohol or a narcotic; and the result is usually the same as with men who have no medical training to protect them against delusion in such matters. Under such circumstances the spirit of kindness to the erring generally prompts those who comment on the occurrence to seek out its mitigating circumstances, and to dwell upon them, so as to shield the reputation of the victim as much as possible. This, however, we believe to be more creditable to the hearts of those who discuss so unfortunate an event than to their heads. It would be more likely to prevent the repetition of careers of this sort if a little wholesome truth followed each one. The fact is that physicians, of all men, ought to understand that it is a shame and a disgrace to yield to the seductions of stimulants or narcotics. They know, better than any other class in the community, the peril of trifling with such things, and they have no excuse for indulging a dangerous taste for them. It is probable that men who fall victims to the cocaine, or opium, or alcohol habit are men of weak will, although they may disclose their weakness only in this way. But no medical man can be excused who begins the "easy descent to Avernus," for medical men who do this sin against light; and such errors would probably be less numerous than they are, if the plain truth were told about them. The adage "*nil nisi bonum de mortuis*" has something very attractive in it; but it ought not to stand in the way of truth.

CAMPHORATED NAPHTHOL.

It has recently been found that naphthol, which is very insoluble in water, can be combined with camphor so as to form a liquid. It is only necessary to rub up one part of naphthol with two parts of dry camphor, to obtain a creamy liquid. This product is of a pinkish color if the naphthol is not pure. It has been found to be an excellent antiseptic application to wounds and ulcers, and is said to clean off the false membrane in diphtheria.

IMPOSING ON A PHYSICIAN.

It is almost incredible, but what was printed as a joke in the REPORTER some months ago has been actually put in practice in France. According to the *Gazette Hebdomadaire*, Feb. 1, 1889, a physician in a town in France was called up from his bed on a stormy winter night and implored by a peasant to come to see his child, who was suffering with an affection of the throat which threatened strangulation.

To the hesitation of the doctor to go a distance of five or six miles, he replied that he had come all the way on foot, and it was not too much to ask the doctor to go to such a desperate case. Reluctantly the doctor yielded to his sense of duty, had his carriage made ready, and then, taking his summoner with him, drove to a little village six miles away to see the patient. Arrived here, he gained access to the house with difficulty and found a child with no appearance of illness whatever. The father professed great astonishment, and protested that when he left the child it appeared about to die. With thanks to the doctor, and imitation of the symptoms of the child at an earlier hour, he allowed the physician to make his way home.

A few days later the doctor learned that just before he called him, the man had been in the town on a drinking bout, and had made a bet with a companion that he would not walk home. He won his bet at the expense of the doctor.

It is hard to believe a story of this kind, and yet it is not absolutely beyond belief. The correspondent who communicates it to the *Gazette Hebdomadaire*, couples it with another, to indicate the trials which may meet a physician in the discharge of his duty, and asks what can be done to punish those who could thus impose on the sense of duty and humanity of physicians? Some punishment a wretch of this kind ought to have; but he might better receive it from his fellows than from anyone else, for they would probably find whom the trick hurt most the next time one of them really needed medical aid at night.

The story is mainly interesting as showing that the experience of physicians is pretty much the same all the world over, and that they must expect to make certain sacrifices, for the sake of their calling, not only to the needs of their patients, but also to their ignorance or even their baseness. It is in the face of just such imposition as this story illustrates that the nobility of the medical calling shines brightest.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY.—The members of the Philadelphia County Medical Society are informed that any member who has an appointment to read a paper before the Society will have it set up in type and two galley-proofs furnished him on or before the day of the meeting, provided his copy is placed in the hands of the Editor of the Transactions at least a week before the time it is to be read. This regulation must prove of great convenience to the authors of papers.

PUBLISHING LECTURES WITHOUT PERMISSION OF THE AUTHOR.—On January 7, 1889, Judge Allison made a decree in Court of Common Pleas No. 1, making perpetual the injunction which restrains Walter B. Saunders, a publisher of Philadelphia, from publishing and selling books on general and medical chemistry made up of condensations from lectures delivered at the University of Pennsylvania by Dr. Theodore G. Wormley, Professor of Chemistry and Toxicology in the Medical Department of that institution. The defendant is ordered to pay the costs of the suit. The action of the Court was based on the fact that the defendant failed to plead answer or demurrer to Dr. Wormley's bill of complaint. This decree of Judge Allison may be accepted as finally settling the question of ownership of oral lectures, and will doubtless hereafter deter anyone from publishing lectures without the owner's permission.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

HANDBOOK OF THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT, NOSE AND NASO-PHARNYX. By Carl Seiler, M.D., Instructor in Laryngology and Lecturer on Diseases of the Upper Air Passages in the University of Pennsylvania, etc. Third edition, thoroughly revised, and greatly enlarged. Illustrated. Small 8vo, pp. 373. Philadelphia: Lea Brothers & Co., 1889. Price $2.25.

The fact that Dr. Seiler's manual of the diseases of the throat and nose has reached a third edition may be taken as an indication that its value as a clear and trustworthy treatise on the subject has been appreciated by the profession at large. The present edition has been fully revised so as to make it conform to the advances in laryngology during the last ten years, and it is an admirable representative of the present standing of this department of medicine. The author's style is interesting and attractive, and his book furnishes abundant evidence of his ingenuity and practical skill. It is so written as to be comprehensible to general practitioners as well as to specialists, and, indeed, it seems to be intended rather for the former than for the latter.

It is handsomely printed, abundantly illustrated, and well bound, and as a book is as creditable to the publishers as to its author.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

217. Functions of a School for Feeble-Minded. By A. C. Rogers, M.D., Faribault, Minn. From the *Proceedings of the Fifteenth National Convention of Charities and Correction*, July, 1888. 5 pages.

218. New Series of Metric Test-Letters and Words for Determining the Amount and Range of Accommodation. By Charles A. Oliver, M.D., Philadelphia. From the *Transactions of the Amer. Ophthalmological Society*, 1886. 3 pages.

219. Cantatory Paresis. By J. Solis-Cohen, M.D., Philadelphia. From the *Medical News*, Oct. 6, 1888. 4 pages.

220. Syphilis of the Larynx, Trachea and Bronchi. By J. Solis-Cohen, M.D., Philadelphia. From the *Transactions of the Philadelphia County Medical Society*, Sept. 12, 1888. 24 pages.

221. Inebriate Asylums and their Work. By T. D. Crothers, M.D., Hartford, Conn. 16 pages.

222. Why Electrolytic Treatment of Stricture Does Not Succeed in all Hands. By G. C. H. Meier, M.D., New York. From the *International Journal of Surgery and Antiseptics*, Oct., 1888. 18 pages.

217. Dr. Rogers's paper is one of great interest to all good citizens, and especially to medical men who have so much influence in determining the treatment of those who are sick or maimed in mind as well as in body. He regards idiots and imbeciles as practically incurable, and recommends placing them in homes where they may lead a happy, harmless and measurably useful life in assisting to care for their fellows.

218. Dr. Oliver's pamphlet is somewhat belated in coming to our table; but it deserves attention because it describes a series of tests for accommodation founded upon careful and accurate study of the conditions essential to accurate determination of the range of this function, which we believe have met the approval of other laborers in the field to which he is specially devoted.

219. Dr. Cohen describes the symptoms and treatment of a condition which is familiar to most persons who sing much, and in which attempting to make a given musical note is accompanied with a sense of weakness or even of pain.

220. This paper of Dr. Cohen's is an elaborate and able review of the subject of syphilitic manifestation in the larynx and lower breathing passages. In it the author discusses the pathology, etiology, diagnosis, prognosis and treatment of the various morbid conditions coming under the classification of his title, in a manner which might be expected from his long study and experience in diseases of this region.

221. Dr. Crothers's pamphlet contains part of a lecture delivered before the Young Men's Christian Association of Toronto, Canada, Oct. 2, 1888. It reviews the history of asylums for inebriates—which we have compunctions about calling "inebriate asylums," and makes a special plea for their usefulness and efficiency in curing the alcohol habit. As the superintendent of a well-known establishment of the kind, and as the Editor of the *Journal of Inebriety*, Dr. Crothers speaks with authority on this subject, and his pamphlet will prove interesting and suggestive to those who have the care of any of that unfortunate class for whom such institutions are provided.

222. This is another pamphlet written to defend Dr. Newman against the reflections of his critics, some of whom have classed him with charlatans, and otherwise indicated undisguised contempt for his methods. According to the old maxim: "*Audi alteram partem*," those who have not done so already might well learn what Dr. Newman and his friends have to say in regard to the comments and experiences of those who think his claims extravagant and his method worthless.

Literary Notes.

—B. Westermann & Co. announce the appearance of the *Microphotographischen Atlas der Bakterienkunde*, edited by Privatdocent Dr. C. Fraenkel and Stabsartzt Dr. R. Pfeiffer. The atlas is to appear in 12 or 15 parts, each containing 10 photograms, and costing $1.50.

—Dr. J. J. Mulheron announces in the *Medical Age*, Feb. 11, that the duties of the chair of Gynecology in the Michigan College of Medicine and Surgery, to which he has been appointed by the Trustees of that institution, added to the cares of private practice, have made it impossible for him longer to edit the *Medical Age*. Dr. B. W. Palmer succeeds Dr. Mulheron as Editor.

CORRESPONDENCE.

Are Medical Witnesses to Be Subjected to New Tests?

TO THE EDITOR.

Sir: The report of the treatment of a medical witness by an attorney in a court in Chicago, as published in the editorial in the REPORTER of February 16, calls us as physicians to be very cautious when we occupy the position of a witness. It is not probable that a respectable lawyer would imitate the conduct of the one referred to in the case reported; but a question concerning the bearing of a quotation from a medical work may be asked by a lawyer in such a way as—unintentionally to him—to lead a medical witness into error, because the attorney has mistaken the sense of the author. Some years ago, the writer was present in court when an important case was on trial. The prisoner was on trial for his life, being charged with poisoning some of his family with arsenic. His lawyer attempted the defense by taking the position "that the persons who died were affected by cholera morbus, a disease in which there are bloody stools." The following symptoms were read from a popular medical author on cholera morbus: "The vomiting and purging are almost incessant; everything taken into the stomach is promptly rejected, the discharges being often brown or blackish, acid, or even bloody." This was read to medical witness after witness, and the question asked each one: "Is the author good authority? Is it as stated?" The question specially included the supposition that bloody evacuations from the bowels were meant by the author.

The writer was not satisfied with the nature of the defence, as he had never observed bloody stools as characteristic of cholera morbus. On his return to his office, he consulted the author. On reading the quotation, it will be observed that, after the semicolon, the purging is not referred to, but the author speaks only of the vomiting. The writer repeated this to the prosecution on the following day, with the statement that the author quoted said nothing about bloody stools. The writer was then called to testify and read the passage quoted, pausing after the semicolon and saying "*semicolon*"; then read the remainder of the sentence, when the attorney said: "That is the way in which *you* read it!" "Yes," was the reply, "and so everybody reads it who reads English correctly." Nothing more was heard of the bloody stools during the trial or in the address to the jury.

The writer was called later during the trial to certify to the correctness of passages from medical writers on epilepsy, etc., etc., but he always asked for the book, that he might read the passage referred to for himself.

The moral learned from this and the late trial at Chicago is, Testify to the truth of no printed or written statement before reading it.

Yours truly,

Easton, Pa., TRAILL GREEN, M.D.

February 21, 1889.

Treatment of Ichthyosis.

TO THE EDITOR.

Sir: I have a case of ichthyosis in a colored girl 8 years old. She is otherwise healthy, and has been affected with the disease three years. The whole cutaneous surface is affected, and the feet often crack so that she cannot walk. I have tried all the usual remedies without avail, or only temporary effect. I should like to ask you or the many readers of the REPORTER if there is any reliable treatment for this most troublesome affection? An answer will greatly oblige,

Yours truly,

E. I. PERSINGER, M.D.

Campti, La.,

Feb. 4, 1889.

[It is presumed, in the attempt to answer the inquiry of our correspondent, that his diagnosis is correct; although the statement that the affection began when the patient was five years old throws some doubt on that point, as the disease is usually noted at the second year. Still the error may have been in the statement of the patient.

Ichthyosis is, so far as our present knowledge goes, an incurable disease. The condition may, however, in almost all instances, be kept under control by judicious management. Internal medication is of no value, although it must be stated that the fl. ext. of jaborandi by promoting the perspiratory secretion appears in some cases to have a slightly beneficial effect. The essential treatment of the disease, however, consists in the use of baths and emollient applications. In the milder cases simple soap and hot water baths, or baths made alkaline by the addition of sodium carbonate or borax, will serve to keep the skin in a comfortable condition. After the bath, which should be taken daily or every second day, a mild ointment should be gently rubbed in. For cases of a more severe type, hot water baths with the use of sapo viridis as the soap are useful, supplemented by the application of one of the several well-known ointments advised in the text-books. An ointment especially to be recommended is one consisting of lanolin with ten to fifty grains of salicylic acid to the ounce. In those rare cases of ichthyosis hystrix, operative measures may be demanded.—Editor of the REPORTER.]

Removal of Gunpowder from the Face.

To the Editor.

Sir: In reading the Reporter of February 2, I was much interested in a communication from Dr. John Gray, having reference to the removal of gunpowder from the face. Last Fourth of July, I treated a similar case, partly by removing the individual powder-grains with a cataract-knife, partly by rubbing the face with moistened surgical gauze, but without waiting for suppuration to occur. The latter method proved, in the aggregate, less painful to the patient and more effective than the use of the knife. The result was very satisfactory, but not so perfect as in the case reported by Dr. Gray.

Yours truly,

Philadelphia, Feb. 11, 1889. A. L. Benedict, M.D.

Good Form in Professional Cards.

To the Editor.

Sir: In the Reporter, February 2, "Country Doctor" asks for a "good form" of medical card. Permit me to offer my country *confrère* the following clipping, not from the *Arizona Kicker*, but from an Arizona weekly of respectability. I do not give the name.

J. E. ——, M.D.,

PHYSICIAN AND SURGEON.

Health Officer, City of ——; for five years County Physician —— County; Medical Director Department of Arizona, G. A. R.; Late Surgeon U. S. Army; for 20 years U. S. Examining Surgeon; the largest Medical Practitioner in Arizona, and charges fees in proportion to his size. His patrons will find it to their advantage to keep healthy.

Office and Dispensary, - - —— Street,
Corner of ——,
——, - - - ARIZONA.

Yours truly,

Pellet.

—Mr. Henry C. Lea has offered to give $25,000 to the Department of Hygiene of the University of Pennsylvania, provided that an equal amount is raised from other sources.

Notes and Comments.

The Disposal of Garbage.

The Philadelphia *Ledger*, Feb. 19, 1889, states that the city of Buffalo has in practical operation a method of disposing of garbage which seems to be entirely unobjectionable, and may be made to pay more than the expenses. The system is known as "the Merz" system. The garbage is hauled to two dryers, each of which receives about 5000 pounds at one charge. Each dryer consists of a double-walled metallic cylinder, between the walls of which steam, at a pressure of about eighty pounds, circulates. Within the driers, rakes made of steam pipes revolve. These also contain steam at 80 pounds pressure; but no steam is admitted to the garbage. That which arises by the drying of the mass is carried off by means of a fan to a chamber, where it is condensed by sprays of water and passes off in an inodorous and harmless stream of water. The heat to which the garbage is subjected acts as a disinfectant, if disinfection be needed. Sixty per cent. of the weight of the garbage is thus removed as water. The dried garbage is afterward put into an extractor, which removes all the grease and oil it contains by the liberal use of benzine. The latter is used over and over again without appreciable loss.

The plant in Buffalo disposes of 30,000 pounds of garbage daily, from which about 1800 pounds of grease is recovered. The dried product is screened, and what is removed is sorted out and finds a ready sale, much of it as a fertilizer. There is only a small residuum, which has to be carted away to serve as filling.

It is said that this method of treating garbage pays a good interest on the investment required. If this is true there should not be much difficulty in having it introduced in all large cities, much to the relief of the health authorities.

At the meeting of the Board of Health Feb. 19, the committee to which had been referred the matter of the proper disposal of garbage presented a report to which was appended a resolution that "it is the opinion of the Board of Health that destruction of garbage by fire is the best plan of disposing of this waste material in the cities," and that the "department having charge of the matter be requested to adopt this method as the one best adapted to Philadelphia, and most conducive to the health and comfort of the community."

Hypodermic Injections of Ergot in Facial Neuralgia.

Dr. J. T. Stewart writes to the *Peoria Med. Monthly*, Jan., 1889, that for the relief of facial neuralgia, hypodermic injections of ergot are incomparably superior to either aconite or gelsemium. He says he has used it during the last six years and has only had it fail in one case, in which there was evidently organic disease. Ordinarily, he says, one injection relieves the pain permanently. Sometimes two, and in one very severe and obstinate case which had gone through the hands of several physicians without relief, it required three. After the third injection, the patient never had a twinge of pain. The injection was made as nearly over the seat of pain as convenient. He uses the plain extract, and has it made on purpose for hypodermic use, so that one minum represents two grains of ergot. Of this solution he uses from eight to twelve minims, blood-warm, at one injection, and without further dilution.

In order to make this treatment a success, he says two things are essential. One is, to have a fresh and pure article of ergot to make the extract from, and the other is, to have the extract reasonably fresh. If kept long, it is not only worthless, but is irritating. When properly prepared and fresh, the injection produces more or less pain for ten or fifteen minutes, and when the pain from the injection subsides the neuralgia is usually gone, and does not return.

He has also used this treatment for sciatica and other forms of neuralgia, but not with very satisfactory results.

Action of Peru Balsam in Buccal Leucoplakia.

Dr. Siegfried Rosenberg communicates to the *Therapeutische Monatshefte*, II, 10, 1888, a paper on the action of balsam of Peru upon idiopathic leucoplakia and other epithelial opacities of the mucous membrane of the mouth. He has employed it locally in different affections of the mucous membrane of the mouth and has found it good. When there is great pain and in persistent rhagades the balsam is painted on with a fine pencil, in the thick insensitive plaques with a bristle-brush, from one to three times a day. Care must be taken to have a pure, good preparation, to admonish the patient to hold the balsam some minutes in the mouth, and not to abandon the treatment too soon—especially in leucoplakia the result is at times somewhat long delayed. Dr. Rosenberg communicates a number of histories of patients, and concludes with the following words: Peru balsam acts as an anodyne in the painful affections depending upon tissue alterations of the mucous membrane; in loss of tissue it hastens skinning over and healing, and causes epithelial opacities to disappear.—*Schmidt's Jahrbücher*, Jan. 15, 1889.

Camphoric Acid in Catarrhs of Mucous Membranes.

Dr. Max Neisel states in the *Deutsche med. Wochenschrift*, XIV, 40, 1888, that he has employed, in Mosler's clinic, camphoric acid in one-half to one per cent. glycerine or alkaline solution in the form of gargles, applications made with a brush, or inhalations, and has obtained good results in slight catarrhs of the larynx, throat, and bronchi. The action of washings of a twenty per cent. alcoholic solution diluted with luke-warm water to one-half or one per cent. was especially favorable in two cases of chronic cystitis.

Given internally, camphoric acid seems to be of advantage in the night-sweats of phthisis. It may be given in capsules containing fifteen or twenty grains.—*Schmidt's Jahrbücher*, Jan. 15, 1889.

Anemone Pulsatilla in Gonorrhœal Orchitis.

Dr. Martel has employed anemone pulsatilla for some years in gonorrhœal orchitis with success. In 1885 and 1886, he reported a series of cases which he had cured with this agent, in doses of thirty drops of the tincture in twenty-four hours. The drug has the advantage of mitigating the pains and enabling the patient to walk. Dr. Bazy has taken up the experiments lately in the Hospital Midi, Paris, and communicates to the *Sémaine Médicale*, No. 2, an account of forty-eight cases so treated. In thirty-five cases, recovery was complete; in ten, there was marked improvement; in two, recovery is uncertain; and in one case, the drug had no effect.

Bazy employs the drug in the following formula:

℞ Tinct. anem. pulsatillæ . . . gtt. xxx
Syrupi . . . . . f℥ iv
M. Sig. Dessertspoonful every two hours.

The remedy is willingly taken and well borne by the patients. Treatment must be continued until complete recovery occurs. The average time required for cure is eleven days.—*Wiener med. Presse*, Jan. 20, 1889.

Disagreeable Effect of Sulphonal.

Dr. J. M. Loebl writes to the *Wiener med. Presse* that his advice was sought by a woman who complained of having been affected with sleeplessness for a long time. The patient looked anæmic, but he found nothing else to account for her sleeplessness. He prescribed thirty grains of sulphonal in two doses, with the direction to take a powder in warm soup or milk one hour before bed-time. When he was called two days later he found the patient in a lamentable condition. She stated that after the first powder she did not obtain much sleep, and on the following day was somewhat deaf. In the evening she took the second powder. After a restless night, in the morning she felt intense headache, dizziness, nausea, sensations of heat and cold. Every effort to rise induced nausea. The skin was cool, the pulse 55. After the patient had taken tea and rum the pulse rose gradually to 70, though the remaining symptoms lasted the whole day and a great part of the night. On the following morning she was able for the first time to resume her household duties, though she still felt giddy. It was then learned that the patient was menstruating, and to this Dr. Loebl was inclined to attribute the whole disturbance, but the patient declared positively that she had never been so affected before, and attributed the condition to the hypnotic.

The author suggests that this case shows that sulphonal can give rise to disagreeable symptoms in some persons—probably in anæmic patients—and that it has a cumulative action.

Fatal Case of Corrosive Sublimate Poisoning After a Surgical Operation.

Professor Wilhelm Weiss communicates an account of a fatal case of corrosive sublimate poisoning after a surgical operation in the *Casopis lékaru Ceskych*, Nos. 1 and 2, 1889. At his clinic on October 19, 1888, a strong woman, 53 years old, had a lipoma weighing twenty-seven and a half pounds removed from the inner surface of the left thigh, and the wound washed with two quarts of a one per cent. corrosive sublimate solution, the wound then appearing to be covered with a fine white coating. The wound was dressed with sublimate gauze bandages. Some hours after the operation collapse and frequent vomiting of a greenish fluid occurred. In the night there were pains in the abdomen, repeated vomiting, and involuntary passage of fetid stools. Opium clysters and stimulants were administered. On the following day there were frequent evacuations with tenesmus, and collapse. Death occurred on Oct. 22, at six o'clock in the morning.

At the autopsy were found acute gangrenous inflammation of the ileum and colon as the result of corrosive sublimate poisoning; also acute parenchymatous degeneration of the kidneys. Weiss thinks that the occurrence of poisoning in this, as well as in most of the cases of corrosive sublimate poisoning occurring in surgical operations, must be attributed to a special idiosyncrasy toward mercury; and he mentions a case seen by him in which, after a single insufflation of a small quantity of calomel, violent stomatitis and other pronounced symptoms of poisoning had occurred. He regards the inflammation of the ileum and colon in corrosive sublimate poisoning as conditions secondary to the primary parenchymatous nephritis, and therefore urges the necessity of being assured before every surgical application of corrosive sublimate that the kidneys are perfectly healthy.—*Wiener med. Presse*, Jan. 20, 1889.

Eschscholtzia Californica: a New Hypnotic.

Ter-Zakariantz speaks highly in the *Semaine Médicale*, No. 52, of a new hypnotic—eschscholtzia californica. It belongs to the family of the papaveraceæ, and he declares it to be both a valuable hypnotic and a very useful anodyne, and, being harmless, preferable to morphine. It can be administered in the form of a potion, of a syrup, or in pills in daily doses of thirty-seven and a half to one hundred and fifty grains. Several formulæ are given by him.—*Wiener med. Presse*, Jan. 6, 1889.

Munificent Gift to the Presbyterian Hospital.

Mr. John H. Converse has about perfected arrangements for the erection of a building, to be given by him to the Presbyterian Hospital, of Philadelphia. This intended gift was referred to in the REPORTER, Feb. 16, p. 215.

The new structure is to be called the Administration building, and will cost between $60,000 and $70,000. It will be an ornamental structure of stone and brick, and will be supplied with all the improvements adapted to a building of the kind. It will be four stories high with a large basement. In the basement there will be offices,

dining rooms for servants, kitchens, pantries, etc. The first floor will contain the office of the superintendent, a surgical clinic room, operating rooms, an apothecary shop, a room for the meetings of the Board of Trustees and the offices of the physicians in charge of the hospital. The second, third and fourth floors will contain the various sleeping apartments for the physicians and nurses.

The Minnesota Medical Act.

Dr. Perry H. Millard, of St. Paul, Minn., writes to the *Journal of the Amer. Med. Association*, Feb. 2, 1889, concerning the work accomplished by the State Board of Medical Examiners of Minnesota in the brief period of its existence, working under the provisions of the present State Medical Practice Act. The statistics are presented with the hope that they may direct the attention of the profession anew to the benefit to be derived, by both the public and profession, from efficient medical legislation, and trusting that they may further stimulate the profession in securing, at the hands of the respective legislatures, now in session, such legislation as is required to protect both the public and the profession. The present Act regulating the practice of medicine in Minnesota, became operative, July 1, 1887, and succeeded the old Act that had been in successful operation for a period of four and a half years. The old Act was a verbatim copy of the present Illinois Act, excepting that the exemption clause was five years instead of ten, which is the period of exemption of the Illinois Act. Through the operations of the old Act the profession of the State had experienced some of the benefits of medical legislation, and was therefore disposed to aid and support the present Act in every way possible. The Minnesota Act has been enforced in a quiet, conscientious and determined manner, by a board composed of the leading representative men of the profession of the State. The Act has received no mention by the medical press of the country, notwithstanding the fact that it is the best Act in existence in any State, and is as ably enforced as any of the various State Medical Acts. The present board has held seven quarterly meetings, at which eighty-six physicians have applied to be examined. Of this number six were refused admission to the class, not having taken three full courses of medical lectures of six months duration each. Of the eighty entering the various examinations, fifty-one were licensed. Some of this number underwent several quarterly examinations before being successful. Twenty-nine were rejected, not possessing the knowledge of medicine required by the board. Of those who passed, forty-nine are Regulars and two Homœopaths. Of those failing to pass the examination, eighteen were Regulars, eight were Homœopaths, and only three were electic physicians. Those passing the examinations of the board were mostly graduates of McGill, Harvard, Chicago Medical, and the University of Michigan. Students who were graduates of the two-term schools and those having sessions of less than six months duration, are of course prohibited the privilege of practice in the State.

American Medical Association.

The Fortieth Annual Meeting of the Association will be held in Newport, R. I., June 25, 1889, under the Presidency of W. W. Dawson, M.D., of Cincinnati, Ohio.

The Chairman of the Committee of Arrangements is H. R. Storer, M.D., of Newport, R. I.

Those who intend to read papers are requested to send word as soon as possible to the chairman of the proper section. The sections and officers are as follows:

Practice of Medicine, etc.—F. C. Shattuck, Boston, Mass., Chairman; G. A. Fackler, Cincinnati, O., Secretary.

Surgery and Anatomy.—N. P. Dandridge, Cincinnati, O., Chairman; W. O. Roberts, Louisville, Ky., Secretary.

Obstetrics and Diseases of Women.—W. H. Wathen, Louisville, Ky., Chairman; A. B. Carpenter, Cleveland, O., Secretary.

State Medicine.—J. Berrien Lindsley, Nashville, Tenn., Chairman; S. T. Armstrong, U. S. Marine Hospital, New York, Secretary.

Ophthalmology.—Geo. E. Frothingham, Ann Arbor, Mich., Chairman; G. C. Savage, Nashville, Tenn., Secretary.

Laryngology and Otology.—W. H. Daly, Pittsburgh, Pa., Chairman; E. Fletcher Ingals, Chicago, Ill., Secretary.

Diseases of Children.—J. A. Larrabee, Louisville, Ky., Chairman; C. J. Jennings, Detroit, Mich., Secretary.

Medical Jurisprudence. — W. Kiernan, Chicago, Ill., Chairman; T. C. Evans, Baltimore, Md., Secretary.

Dermatology and Syphilography.—L. Duncan Bulkley, N. Y., Chairman; W. T. Corlett, Cleveland, Ohio, Secretary.

Oral and Dental Surgery.—F. H. Rehwinkle, Chillicothe, O., Chairman; E. S. Talbot, Chicago, Ill., Secretary.

NEWS.

—The Swedish government has permitted cremation under certain medical and clerical restrictions.

—Fifteen hundred physicians attended the third Russian Medical Congress held at St. Petersburg Jan. 15.

—Hiram Vandusen, of New York City, asserts that he has lived for sixty-five days on Vichy and Croton water.

—The will of the late Alexander Murray, of Montreal, bequeaths to the Montreal General Hospital the sum of $750,000.

—The son of Dr. Jacoby, a boy 11 years old, was recently cremated in Paris. This is the first cremation that has taken place there.

—The *Lancet*, Feb. 9, announces that Dr. H. Frémy has been sent by the French Government to Colorado to study its climate.

—The Moral Reform Union of England has been exerting its influence to prevent the employment of children of a school age at theatres.

—The deaths in Philadelphia for the week ending Feb. 23, numbered 347. There were 11 deaths from scarlet fever, 18 from typhoid fever, and 7 from diphtheria.

—The *Lancet*, Feb. 16, says the Russian Government has found it necessary to issue a regulation forbidding female medical practitioners to attend adults of the male sex.

—Dr. William Pepper, Provost of the University of Pennsylvania has announced that during the coming year it is proposed to put up a dormitory building for the accommodation of the University students.

—The *British Med. Journal*, Feb. 9, states that Dr. Fancourt Barnes's "Manual of Midwifery for Midwives" has been translated into Burmese by order of those in charge of the Countess of Dufferin's Fund.

—An extensive epidemic of a scarlatinal character is said by the *Lancet*, Feb. 16, to prevail in and around Macclesfield. Upward of a hundred cases have already occurred, and some deaths have been reported. The milk supply is suspected to be the source of the poison.

—A state vaccine institute has been established in Italy by Royal decree. It will be under the direction of the Department of Public Health and of the Ministry of the Interior. The Committee of Management consists of Professor L. Pagliani, Dr. Felice Baroffio, and Prof. Davide Toscani.

HUMOR.

IT IS DOUBTLESS A KNOWLEDGE of the fact that every one can see through it that causes the window pane.—*Life.*

NEEDED A CHANGE.—Doctor—"What your husband needs, Madam, is change of scene."

Mrs. De Temper—"Do you think he should go off for his health?"

"Well, it doesn't matter which goes—you or he."

"THE EDITOR down the street," writes a Kansas editor, with withering scorn, "should go to school during the winter months, so that the teacher can learn him something about grammar. We have seen bad writers before, but we never seen one who could crowd so many grammatical erratum into a single sentence."—*Kansas City Star.*

A WISE MEDICINE MAN.—Dr. Ebbonie—"Dat chile o' yours am lookin' poo'ly, Mrs. Yallerby. What's he done gone an' swallowed this time?"

Mrs. Yallerby—"A bit ob lead-pencil, docto'."

Dr. Ebbonie—"H'm! What he wants now, ma'am, am an erasive remedy. I recommend him ter chew a piece ob Injy-rubber half an hour afore each meal."—*Puck.*

A PLACARD placed on the window of a shoemaker's shop near Cripplegate, London, many years ago, is said to have read as follows:

Surgery
performed on aged
Boots and Shoes
broken Legs sett and bound upright
disordered feet repaired
the wounded heeld,
The whole Constitution mended
and the Body supported
by
a new Sole. By T. T.

OBITUARY.

WILLIAM WEIGHTMAN, JR., M.D.

Dr. William Weightman, Jr., died at his residence, Falls of Schuylkill, Feb. 10. Dr. Weightman was born in Philadelphia October 10, 1845. After a thorough school education he studied medicine at the University of Pennsylvania, from which he was graduated with honors. Immediately after graduating he entered the employ of Powers & Weightman, manufacturing chemists, and was admitted into the firm in 1884, soon afterward taking charge of the works at the Falls of Schuylkill.

715-717 MARKET STREET PHILADELPHIA.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

ANÆSTHETICS.[1]

BY J. WILLIAM WHITE, M.D.,
PHILADELPHIA.

DEMONSTRATOR OF SURGERY; CLINICAL PROFESSOR OF GENITO-URINARY DISEASES; SURGEON TO THE PHILADELPHIA, GERMAN AND UNIVERSITY HOSPITALS.

Gentlemen: The various methods of producing anæsthesia for surgical purposes at the present day are deserving of the most careful study and consideration. The number and variety of surgical operations have so enormously increased under the influence of the discovery of antisepsis that the problem of how most safely to produce unconsciousness has become one of correspondingly increased importance. I shall try to review the subject as well as can be done within the limits of an hour, confining myself to the fundamental principles involved and using freely such teachings and writings as are considered authoritative.

The agents employed as anæsthetics may be included under the following heads: 1. Alcohol. 2. Chloroform. 3. Ethers. 4. Methylene 5. Nitrous Oxide.

The first four in all probability act in a somewhat similar manner in producing anæsthesia, *i.e.*, they directly affect the nerve centres; but their secondary effects are altogether different.

Alcohol may be dismissed in a few words. The narcosis which it produces when swallowed is unfortunately familiar by observation to almost every one, in the shape of profound intoxication, but it may also be brought about by inhalation as is the case with the other anæsthetics. Alcoholic narcosis, however, is much more persistent and consequently much more dangerous than that of the more volatile anæsthetics which are absorbed and eliminated with greater rapidity. Unconsciousness can be produced in this way only by a much greater expenditure of time. The preliminary period of excitement is vastly

[1] A lecture delivered to the Graduating Class of the University of Pennsylvania, Session 1888-1889.

more prolonged, the patient is far more uncontrollable, and the resulting narcosis will sometimes persist for hours. The drug is therefore not used at the present time as an anæsthetic, and requires no further consideration.

Chloroform.—In this country chloroform is employed as an anæsthetic, by the great majority of surgeons, only in those cases in which the other anæsthetics have failed, or in those exceptional operations, such as staphylorraphy, in which it is especially desirable to prevent coughing and the hypersecretion of bronchial and laryngeal mucus. It is still used largely in obstetric practice, and is said to be far safer when given to children than when employed with adults. So far as I know no satisfactory explanation of this fact, if it be a fact, has yet been advanced.

Chloroform undoubtedly has certain advantages over ether. It is cheaper, it acts in smaller quantity, its local anæsthetic action is greater than that of ether, and hence there is not so much mucus thrown out from the throat and lungs; it is not so apt to be followed by nausea and vomiting; being less volatile it does not so completely fill the pulmonary spaces with its vapor, and there is less of the suffocating feeling which most patients have when they take ether.

These are, I believe, all the advantages that can possibly be claimed for chloroform. To counterbalance them we have the one all-important fact, that chloroform has killed about one person out of every 2600 to whom it has been administered. The individuals to whom it is safe to give it cannot with any certainty be selected beforehand. In many cases the autopsies have disclosed no evidence of disease of any sort. The patients have simply died "poisoned."

We have, as yet, no conclusive evidence or statistics to enable us to balance the merits of the different anæsthetics in a perfectly mathematical manner. We know that between the years 1870 and 1885, 184 deaths have been published in England as occurring under chloroform, which is slightly over 12 in a year. The number of times that chloroform has been administered in the same period is not known. At Saint Bartholomew's from 1875 to 1880, chloroform had been used 4810 times with two deaths. Mr. Williams has recorded, as his personal experience, 208 cases of chloroforming with one death. On the other hand, between 1870 and 1885, 28 cases of death from ether in England alone have been recorded. Saint Bartholomew's tables give 6440 cases with two deaths; Mr. Williams 1050 cases with one death.

Of course, in giving any anæsthetic it is highly important that the lungs, the heart, and the kidneys should be sound. But this is far more important or essential in giving chloroform than in giving any of the others. It has so high a boiling point and is therefore volatilized with such comparative slowness that it is probably never eliminated entirely by the lungs, but only with the aid of the excretory organs generally.

If the lungs have a smaller area than usual on account of disease, just so much more strain is thrown on the kidneys, and if in addition they are contracted or fatty, the danger is greatly increased. It is, however, usually by its depressant action on the heart that chloroform kills, and it seems highly probable that it often does this by the property which it has been shown to have, of destroying the contractile power of the cardiac muscle when it reaches it in a sufficiently concentrated form.

Various circumstances may greatly affect the degree of its concentration in the lungs and circulation, and thus increase, or decrease, the danger of its employment. Of these the most important are those connected with the character of the respiration of the patient and the circulation through the lungs. For example, a given quantity of chloroform, say one drachm, will exert its greatest effect when the respiration is deep and quick, because the vapor is then carried, in any given moment of time, in larger quantity into the air spaces of the lungs. If, at the same time, the patient, being only partially anæsthetized, stops suddenly after breathing deeply, *i. e.*, closes his glottis and strains, he increases the rapidity of absorption of the chloroform vapor into the blood; or if the movement of blood through the lungs is exceptionally slow as shown by a dusky or congested appearance of the face, the opportunity for absorption will likewise be greater, and the blood will reach the heart overcharged with chloroform, and possibly produce its poisonous effect. A low temperature of the blood of the patient, as in cases of shock, seems to act in the same manner, probably by hastening the condensation of the chloroform vapor in the pulmonary tissues and favoring its absorption into the blood.

A combination of these conditions therefore should put the anæsthetizer, especially one who employs chloroform, on his guard. And, during the preliminary stages of chloroformization, at least, it may be said that a

patient who is shocked by injury or accident, who is only partially anæsthetized, whose face is dusky or congested, whose breathing is quick, and who is struggling against the anæsthetic, is in the greatest danger. Many deaths have occurred from chloroform under these circumstances and in this first, or so-called stage of excitement. The second stage is the period of true anæsthesia, during which consciousness and sensibility are abolished, the muscles relaxed, the pulse weak, the breathing often shallow and feeble; it is during this stage that operations should be performed and great care observed to limit the quantity of chloroform used to the least amount necessary to continue the condition without causing it to pass into the third stage, or that of narcosis in which there is increasing weakness of the pulse, stertorous breathing, complete abolition of the reflexes and other indications of profound involvement of the nerve centres. This is still more dangerous than either of the other stages. There may be no premonitory symptoms of danger, or it may be indicated by either great paleness or congestion of the face, or by marked irregularity and failure of the pulse.

It seems probable that the position of the patient during chloroforming has much to do in increasing or diminishing the risks of perspiratory or cardiac failure. It is said that during gynecological and obstetric operations, in which the patients are kept lying on the left side, the pulse and respiration have been more satisfactory during anæsthesia from chloroform than when the patients have taken it in the usual position. A celebrated surgeon is said to have noted the fact that all of his patients who, when in danger of death from chloroform, were rolled upon the left side recovered, while those kept on their backs or placed in other positions not infrequently died. It may be that the view which attributes special safety to the drug in obstetrical cases took its origin in the fact that the customary obstetrical position in England is upon the left side. Dr. Buxton thinks that the influence of position is unquestionably important and is due to the fact that the condition of the heart, lungs, tongue, and larynx is more nearly correct physically and physiologically when a patient is placed in the left lateral position instead of on the back. He mentions as corroborative the circumstance that during sleep and in all conditions in which respiration is shallow and is carried on at a disadvantage, most persons instinctively assume the lateral position. He adds that the difference in the condition of the pulse and respiration of patients chloroformed in the dorsal and lateral positions has been so striking as gradually to force on one the lesson of placing every patient where it is possible on the left side before chloroforming him.

Various apparatuses have been devised for the administration of chloroform, most of them too complicated and expensive for practical use. In my opinion the safest and therefore the best way of giving it is by pouring a few drops at a time upon the surface of a folded towel or napkin and, holding it at first two or three inches from the nose of the patient, gradually lessening the distance as its effects begin to be produced. It should always be given while the patient is in a reclining or recumbent posture, being especially dangerous on account of the tendency of heart failure if it is given to persons in an erect or semi-erect position. During its administration certain indications should put the anæsthetizer immediately upon his guard. These are, in the order of their danger, first, failure of the pulse; second, sudden change in the color of the face, extreme pallor denoting a tendency to syncope while a dusky or purplish face indicates obstructed respiration; third, stridulous breathing; this if very marked may indicate spasm of the glottis either from direct irritation by the chloroform vapor, or from reflex action caused by the operation which may have been begun; or the same breathing may be produced by the falling backward of the tongue and epiglottis, which thus cover more or less completely the aperture of the larynx.

These conditions, while more likely to occur during anæsthesia from chloroform, may also be produced by ether and other anæsthetic agents. The duty of the anæsthetizer should be the same in every case. He should promptly take the following precautions:

1. Remove the anæsthetic and secure a plentiful supply of fresh air about the head and face of the patient.

2. Place the fingers back of the angles of the inferior maxilla and press it strongly forward, thus carrying with it the tongue.

3. Seize the tongue near its tip and draw it forward.

4. Lower the head of the patient or, if the case is a grave one, raise the lower limbs, pelvis, and trunk higher than the head and shoulders.

5. Begin the movements of artificial respiration, catching the arms at the elbows and carrying them outward and upward

until they almost meet in a line above the head, then bringing them down again until they touch the sides of the chest; at each movement moderate pressure should be made upon the lower portion of the sternum These motions should be repeated not oftener than 16 or 18 times per minute. This time honored method of artificial respiration has never been improved upon, and a large quantity of air can be made to pass through the lungs with each of these movements.

6. Dash alternately hot and cold water on the front of the chest.

7. Give hypodermics of strychnia.

8. Rub the extremities strongly toward the heart.

9. Compress the abdominal aorta.

The last two methods are intended to keep the blood in the region of the heart and great nerve centres where, at least during the period of shock, its presence is vitally important.

10. Faradize the diaphragm, placing one pole on the pit of the stomach and the other over the root of the neck.

11. Small lumps of ice, or "ice suppositories," inserted into the rectum, will sometimes by reflex action bring about deep breathing.

12. As soon as swallowing returns use diffusible cardiac stimulants—alcohol, ammonia, and possibly digitalis. The majority of these directions apply also to difficulty arising during the use of ether, which we may now consider.

ETHER.—Ether is the chief anæsthetic employed in practical surgery in this country. It produces when inhaled a succession of conditions very like those described as caused by chloroform, but with important differences.

1. A stage of excitement preceded by a feeling of strangulation or of suffocation, with a burning sensation in the fauces, lachrymation, often more or less coughing, accompanied by excessive secretion of laryngeal and bronchial mucus. In other words, we have during this period of excitement the evidences of the local, irritating action of the ether upon the mucous surfaces with which it comes in contact. The patient may at this time pass into a condition closely resembling natural sleep, often mistaken by inexperienced etherizers for one of true anæsthesia. During this condition the patient can easily be aroused and is sometimes quite conscious of all that is going on about him. Indeed, during the whole of this stage the special senses are often almost preternaturally acute, and a remark made by the surgeon or his assistant will often be responded to promptly and intelligently by the patient.

2. This passes after a variable interval into a period of unconsciousness, at first accompanied by some degree of muscular rigidity, but soon followed by relaxation. The complexion should be unaltered; the pulse is usually increased in force and volume.

3. If the etherization is pushed and a large quantity of the anæsthetic employed a stage characterized by stertor and profound coma follows, the pulse being still strong and full but the face becoming flushed or purplish. This stage should only be occasionally and accidentally reached during etherization, and should be the signal for the temporary withdrawal of the anæsthetic and immediate inspection of the respiratory conditions with careful attention to the mouth and throat and watchfulness to see that the tongue is well forward, and the movements of breathing deep.

It cannot be said that ether is absolutely safe and harmless under all circumstances, as there have been a number of deaths reported from its use or, at least, during its use. In the great majority of these cases the exact responsibility of the anæsthetic itself has never been determined.

In 1861, a committee of the Boston Society for the Improvement of Medical Science reported that after a labored search they had learned of no case which was unquestionably and unavoidably fatal from the breathing of pure sulphuric ether. They considered two conditions essential to placing the responsibility of any case of death upon the anæsthetic: 1. That the event should occur while the patient is actually anæsthetized. 2. That the circumstance of its occurrence should be inexplicable by any phenomena of disease or by the operation. Very few, if any, reported cases comply fully with these conditions.

The deaths recorded by Turnbull and Lyman in their treatises, and by Jacob (*British Med. Journal*), are either uncertain in their relation to etherization, or were caused by asphyxia, or more rarely by syncope.

Druet (*Des Contraindications de l'Anæsthesie*, 1880) and Kappeller (*Deutsche Chirurgie*, 1881) give no new light on sudden deaths occurring during anæsthesia, and accompanied by cessation of respiration. The cases of Hunt, Morton, Levis, Hutchinson, Norris, Sims, Emmet, and others, are all instances of death after anæsthesia,

at periods ranging from two hours to eighteen days, and possibly associated with nephritis.

One reported by Allier and two by Post occurred during operations for tumors of the neck. In connection with these the observation of Schiff should be remembered, that when animals are anæsthetized, pinching the skin of the neck will at once arrest both respiration and the action of the heart.

In several recorded cases, while herniotomy was being performed, the patient vomited and died. Mr. Marcus Gunn has suggested that as the vomiting of acute intestinal obstruction results from a powerful descending impulse of the vagus, and as sudden arrest of the heart's action in diastole is also known to be produced by such an impulse, we may expect to meet with this association of vomiting and sudden heart-failure during as well as before and after anæsthesia. The same result has occurred even more frequently under other anæsthetics.

Warrington Hayward records a death during etherization from the sudden failure of respiration owing to the occurrence of an epileptiform spasm of the respiratory muscles, whereby the chest was fixed in the position of expiration. Nothing was discovered either at the time or at the autopsy, which gave any clew as to how the fatality could have been avoided.

The doctrine of cerebral inhibition advanced by Brown-Séquard should not be overlooked in its application to the few cases of sudden death during etherization in which the autopsies failed to explain the accident. He has shown that there is an arrest or suspension of function in the nerve centres, muscles, and nerves, taking place without demonstrable organic change, and following immediately upon irritation of the nervous system at some point more or less distant from the part in which the effect is observed. He attributes to this cerebral inhibition the cases of sudden death and "death without agony" which are analogous to the loss of inteilectual activity that occurs in epilepsy. Such death may be produced in animals by a prick of the ventricle of Arantius in the floor of the fourth ventricle.

But one instance of death during etherization has come under my immediate notice. A middle-aged man, apparently healthy, came to Philadelphia from the northern part of this State to have an operation for the relief of hemorrhoids performed by Dr. Agnew. After the customary preparations, the administration of ether was begun, and progressed until the second stage was reached, muscular rigidity not having entirely disappeared. Sensation having been abolished, however, the operation was begun and one hemorrhoid was ligated, when the patient suddenly ceased to breathe. Every effort was made to bring about natural respiration, but without success. The entire quantity of ether given did not exceed four ounces. The autopsy showed that death had resulted from an apoplexy into the fourth ventricle, a small coagulum being found in that position and resting upon the respiratory centre. The vessels of the circle of Willis were brittle and atheromatous, as were also the vessels of the entire brain. The increased vascular tension produced by the ether was probably the immediate cause of death in this case, but of course the anæsthetic should not be held accountable for the death, as any other condition which would have increased the blood-pressure would have produced the same accident.

Dr. Fritz Feuter has recently published an elaborate article upon ether anæsthetization, recording his experience in a large number of cases. He has always employed a large face mask, around the edges of which a folded towel is laid to prevent evaporation of the drug.

The following four points were separately dealt with, as being of most importance: First, the time from the beginning of anæsthization until anæsthesia is produced. Second, the quantity of ether necessary for this. Third, the total quantity of ether used; and fourth, the duration of the anæsthesia. His method of administration is as follows: From a graduated bottle about 50 Ccm. is poured upon the mask (for an adult, for children half this quantity is sufficient). The mask is then slowly brought down to the face so that the patient gradually becomes accustomed to the fumes; this does away with that painful choking which always occurs if the mask is abruptly placed upon the face. So soon as the mask is well over the face a folded towel is placed around it, and the mask is not removed again until there is complete relaxation of the extremities. In this way the patient is continually inhaling ether fumes, for even his exhalations are partly reinhaled, and assist in producing anæsthesia. With these precautions carefully adhered to, the author has invariably found that complete anæsthesia could be induced within two minutes. More than this, the amount of ether subsequently required to maintain unconscious-

ness is remarkably small. Often in operations of over a half hour's duration, and even longer, no addition of ether was necessary.

In his opinion the two most important points upon which the success of etherization depends are the concentration of the fumes and the non-removal of the mask. The nausea following etherization he believes to be due to the swallowing of saliva which is filled with ether, the secretion being greatly increased by the drug; naturally, therefore, the less ether used the greater probability that nausea will not be produced; and indeed his experiments seem to justify this conclusion, for in one hundred and fifty cases vomiting only occurred in ten, and in two of these the patients had taken a meal immediately before the operation. In quoting the statistics of other clinics, he states that out of five hundred and fifty-three cases vomiting occurred in one hundred and forty-eight. Feuter continues by giving a list of personal observations which differ but slightly from those of other practitioners. One fact, however, deserves special notice, viz., he has observed in several cases that when the patient had taken a moderate quantity of alcohol just previous to the operation that the anæsthetization was greatly accelerated; indeed, in one instance hardly a minute passed before the patient was in a complete stupor. Emmet was the first to point out the danger of etherizing patients affected with nephritic troubles. He claims that it is absolutely necessary to examine carefully the urine of such patients before operating, and holds that the presence of albumin is a positive contra-indication for the use of ether, and direct indication for the use of chloroform. Other authorities are of the same opinion. In direct contradiction of the above statements, Feuter declares that he has frequently etherized patients with albuminuria without dangerous symptoms resulting.

Dr. Robert Lovett has reported lately some careful observations in a series of sixty consecutive cases at the Boston City Hospital. He used two methods; one, which he calls the gentle method, in which the ether was given slowly and cautiously; the other the "forcible" method, in which the cone was at once applied closely to the nostrils and mouth of the patient. The former method required an average time of 9.3 minutes and an average amount of 2.5 ounces for complete anæsthesia. The latter only required 4.4 minutes and 1.5 ounces, but the choking sensation was very much aggravated and the patients were very apt to react and struggle violently if they got only a breath of air.

I may say that this experience about corresponds with that of Dr. Agnew and myself in the use of a rapid method by which the ether contained in a bottle was dropped into a bucket of hot water by the bedside of the patient, the vapor being conveyed by a long flexible tube to a mask placed tightly over the mouth and nose of the patient. Our average time for producing insensibility in some dozens of cases was considerably less than a minute—about 43 seconds, and was often within a half-minute; but the condition was rather one of asphyxia than of true anæsthesia; the distress of the patients was very great, and the evidences of excessive increase of vascular tension were so unmistakable and sometimes so alarming that after a fair trial we gave up the method, believing that no economy of time or of ether would compensate for the slightest increased risk to the patient.

On the whole, it may be said that there is no perfectly satisfactory evidence that ether *per se* ever kills, and although it undoubtedly may do so by producing asphyxia, in the vast majority of cases it will do this so slowly and give such marked evidence of its threatening action that every opportunity will be afforded the etherizer to avoid or prevent it.

There is hardly a case in which ether can not be given with safety, but there are certain classes of cases in which there is special danger. These are: 1. Very old people with emphysema, fatty heart, hypertrophy or valvular disease of the heart. 2. Persons with marked tendency to weak heart action or syncope. 3. Persons with extensive lung disease, or with lungs greatly tied down by old pleuritic adhesions. 4. Habitual drunkards. 5. Persons who as the result of alcohol, syphilis, gout, rheumatism, or old age have marked evidences of extensive atheromatous disease.

In the presence of any of these conditions ether should be given very slowly with a large admixture of atmospheric air, and with great attention to the pulse, complexion, and the movements of breathing. The following rules, many of them almost self-evident but all of them important, apply to the preparation of a patient not only for etherization but for the administration of any anæsthetic.

1. The stomach should be empty. No hearty meal should have been taken for at least six or eight hours before the operation.

It is a good rule to insist that all nourishment taken on that day shall be liquid or nearly so, and in many cases it is well to limit the patient to a glass of milk taken early in the morning. This precaution lessens the risk of solid morsels of food being drawn into the air passages during vomiting; makes vomiting less frequent and severe; and diminishes subsequent nausea. In addition, it may be said that the presence of any large quantity of food in the stomach may embarrass respiration by interfering with the action of the diaphragm.

2. Loosen all garments that could in any way impede the movements of respiration or those, such as tight collars or neckbands, which could obstruct the flow of blood through the great vessels of the neck.

3. Remove false teeth or plates from the mouth. Never neglect to inquire as to their presence, no matter what may be the apparent age of the patient.

4. Keep the room at a temperature of at least 68° F. or 70° F., or if the operation is to be a prolonged one at 72°. Practically this is an excellent rule because patients often take cold by exposure during etherization. There is also an additional theoretical basis for it in the fact that when the blood and pulmonary tissues become saturated with ether, evaporation takes place from the surface of these tissues, causing a rapid loss of heat. If the air inspired is warm this supplies the heat necessary to volatilize the ether; if the air is cool the heat of volatilization is taken from the surrounding tissues, quickly chilling them, producing violent contraction of the capillaries, prolonged stasis, engorgement of the right side of the heart, and asphyxia.

5. Have the room perfectly quiet. The preliminary stage of etherization is, as has been said, one of acute sensitiveness to external impressions, and may be greatly prolonged by noise, bustle or excitement in the room.

6. Always examine the heart and lungs, and if the operation is to be severe or prolonged, examine the urine previously.

7. See that no light or flame is near the ether, especially on a lower level.

8. Quietly tell the patient in advance what to expect. Explain the suffocative feeling, mention that it is of almost invariable occurrence and is of no importance; describe the proper method of breathing through both the mouth and nostrils; caution the patient against struggling and resisting. Do this quietly and gently, and it is astonishing how often it will secure such intelligent co-operation on the part of the patient as will make the etherization rapid and easy.

9. Have an assistant ready to render whatever aid may be required, and, if inexperienced, caution him against the use of unnecessary force.

10. Of the various apparatuses employed for the purpose but two need be considered. One of these, that devised by Dr. Allis of this city, consists of a wire frame work, large enough to cover the lower part of the face and through which a strip of bandage has been passed to and fro so that numerous folds are exposed to the wetting action of the anæsthetic. These large evaporating surfaces, the thorough admixture of air, and the economy of ether are the three most definite advantages of this excellent little apparatus. An ordinary towel if folded into a cone, an aperture being left at the apex large enough to insert a finger, answers every purpose in private practice and obviates the necessity for carrying the more cumbrous inhaler.

11. The etherizer should watch three things —the breathing, the complexion, the pulse. When the breathing is regular and full without snoring, there can be little if any danger; if it is shallow and interrupted, watchfulness should be redoubled and a plentiful admixture of air given with the ether. If it ceases, the anæsthetic should be instantly removed and the tongue drawn forward; if respiratory movements do not begin, artificial respiration should be employed. If the face is very pale and the skin cool, the head should be lowered; if the complexion is livid or purplish, the head should be raised slightly, a freer supply of air given and the tongue and lower jaw brought forward. In case of failure of the pulse the head should be rapidly lowered, the ether immediately withdrawn, and hypodermics of whiskey and digitalis administered. Occasionally in patients who have been etherized after having eaten heartily, a condition may be noticed which includes to all appearances several of these elements of danger, but which is precedent to the act of vomiting; the breathing becomes irregular and interrupted, the face cold and pallid, the pulse almost indistinguishable. In the vast majority of cases this is followed by an expulsion of the contents of the stomach and then by the disappearance of these alarming symptoms. It should not be forgotten, however, that in exceptional cases death may occur during vomiting, possibly, as has been mentioned above, from the

descending excitation of the pneumogastric arresting the heart's action in diastole. This affords an additional reason for forbidding the taking of food for some hours previous to the administration of an anæsthetic.

A recent suggestion of Dr. Benjamin Howard, as to the cause of death in certain hitherto unexplained cases of fatality during anæsthesia, seems to me worthy of the most careful consideration. His views are founded upon his own observations and upon those of Dr. R. L. Bowles, made many years ago in conjunction with Drs. Fox, Hunter and Marshall Hall. Dr. Bowles claims precedence, I believe, for his work, but agrees in the main with Dr. Howard's views, which are as follows: A certain number of cases of apnœa and death are due to falling backward of the epiglottis, a condition often unrecognized, and almost surely fatal if unrelieved. There are many reasons for believing that traction on the tongue or pushing the jaw forward, while of the utmost value when the tongue itself is the obstructing body, do not affect the position of the epiglottis in these exceptional but equally dangerous cases:

Traction on the tongue is ineffectual because:

a. The tractile force supposed to be exercised upon the epiglottis is arrested chiefly by the frænum linguæ, and through the muscular fibres within it is expended upon the inferior maxilla into the genial tubercles of which they are inserted.

b. The surviving force is expended almost entirely upon, and intercepted by, the anterior pillars of the fauces.

c. For any tractile force which may survive, a continuous and sufficient medium for its transmission to the epiglottis is wanting.

Extension of the head and neck is the only sure means of causing instant and complete elevation of the epiglottis, because: by a three-linked chain, in which the hyo-epiglottic ligament is the lower link, the body of the hyoid bone the central link, and the combined genio- and mylo-hyoidei muscles the upper link, the epiglottis is so connected to the body of the inferior maxilla, that above a certain point, as the body of the lower jaw is moved upward, the epiglottis instantly, irresistibly, and inevitably moves upward exactly in unison till it is erect. The violent wrenching asunder of the clenched teeth, in proportion as it depresses the body of the inferior maxilla antagonizes a distinct effort of Nature to maintain the elevation of the epiglottis.

Having, by bringing the patient to the edge of the table or bed, or by elevation of the chest, provided that the head may swing quite free, with one hand under the chin and the other on the vertex, steadily but firmly carry the head backward and downward. The neck will share the motion, which must be continued until the utmost possible extension of both head and neck is obtained. Assuming the mouth to be shut and the inferior border of the inferior maxilla to be at a right angle with the cervical column, as in the average recumbent posture, the head must be continued to be extended from thirty to thirty-five degrees more before it is possible for the epiglottis to be affected at all. Not until after the skin from the symphysis to the sternum is quite tense do the relaxed muscles in question beneath it become tense at all. These being tense, from this point the elevation of the epiglottis begins.

In a nut-shell: Make the line of skin from the chin to the sternum as straight as it can be made, and the complete elevation of the epiglottis is assured.

By extension of the head and neck carried to the utmost, the remaining obstructions from the backward-fallen tongue, the velum palati, and uvula, are also simultaneously removed, and the entire pharynx is enlarged throughout. Because: *a*. The tongue, the dorsum of which before fell by gravitation upon the then horizontal posterior wall of the pharynx, falls upon the now horizontal arch of the palate. *b*. The velum palati, by means of the great tension of the palato-pharyngei muscles, is pulled away from the posterior wall of the pharynx, the entire membrane being stretched tightly forward and downward, behind part of the dorsum of the tongue, helping to complete the shutting of the tongue out of the pharynx and into the mouth, and together with its dorsum forming a partition—the anterior wall of a new air-way, thus created and maintained. *c*. The pharynx, anteriorly, from the base of the tongue to the cricoid cartilage, is stretched strongly forward by the extreme tension of the sterno-thyroidei muscles.

Dr. Howard summarizes his interesting paper as follows:

1. Contrary to universal belief, traction of the tongue cannot raise the epiglottis. 2. By sufficient extension of the head and neck, whether by volition, instinct, reflex action, or by the effort of another, whether in the healthy, the dying, or the dead, the epiglottis is instantly, and beyond preven-

tion, made completely erect. 3. By complete extension of the head and neck the tongue and velum are as respiratory obstructions, simultaneously with the epiglottis, removed; and without a moment's delay the entire air-way can be straightened, enlarged, and be made free throughout by the nearest person. 4. If syncope happens to be the chief factor, or only incidental, this also gets thus the quickest and best corrective.

He expresses the hope and confident belief, that the facts above submitted will be found to be permanent additions to our means of averting death.

In the *British Medical Journal*, Jan. 26, 1889, Mr. Frederic Hewitt calls attention, one, to the occasional impossibility of adopting Howard's suggestion, on account of tonic spasm of the muscles of the neck, jaws, etc.; and two, to the danger of trusting to a post oral (or nasal) air-way which might so readily be occluded by tumefaction of the mucous membrane, by mucus, or by morbid conditions. Drs. Martin and Hare, in the *Medical News*, March 2, 1889, reaffirm this latter statement, recommend moderate instead of forced extension of the head and neck, so that space may be left between the tongue and palate to permit of breathing through the mouth, and the simultaneous pushing forward of the hyoid bone and the lower jaw. If obstruction to breathing still persists, the tongue should be at once drawn or pushed forward by force exerted upon its dorsum posterior to the anterior half arches of the palate. The subject is an extremely interesting one, and will bear further investigation; but it would seem now to be fairly well established that in the main Dr. Howard's conclusions are justified, and that his method in the majority of cases and in the absence of nasal obstruction is at once the simplest and the most efficient.

12. The etherizer should attend strictly to the anæsthetic, and unless of long experience and perfect self-possession, to nothing else.

13. Etherization is complete when the arm raised from the side drops helplessly, and when the orbicularis palpebrarum fails to respond when the conjunctiva is touched.

14. After this time the ether should be given in small quantities and with plenty of air.

15. With the completion of the operation the responsibility of the etherizer does not end, although it is not uncommon to see him walk away from the operating table or bedside to inspect a tumor or look at a wound, or aid in washing and cleaning instruments. He should only leave the patient when his place can be taken by a trained and experienced nurse, and should even then for some little time be within call in case of emergency. The vomiting which frequently follows etherization is itself distinctly dangerous if any food has been taken. The patient, incapable of intelligent movement, can readily perish from asphyxia caused by the inspiration of solid portions of the ejecta, and should be carefully watched with this possibility in mind. Then, too, during the intoxication and excitement, which often constitute a distinct stage preliminary to a return of consciousness, he will require careful supervision to prevent him from doing himself harm.

The pain or smarting of the wound will at once draw his attention in that direction and he is very apt to attempt to remove the dressings. The records of surgery show many distressing cases in which this has occurred. One of them, which always seemed to me to be peculiarly horrible, is that of a patient who, being left alone immediately after an operation for strangulated hernia, tore off his bandages, opened the wound and actually pulled out yards of his own intestines.

Methylene.—With this anæsthetic we have had but little experience in this country and I believe that has not been very favorable. It was introduced to the profession twenty years ago by Dr. Richardson, of London, who, after a long series of experiments, concluded that its action was more rapid than that of chloroform and that it produced a more prolonged and profound narcotism, but rapidly escaped from the system, and was accompanied by an equally rapid return of consciousness. Deaths have been recorded from its use both here and abroad, as well as from the use of the methylene ether, a mixture of methylene dichloride and absolute ether, also introduced by Dr. Richardson. I have recently seen this anæsthetic administered by Dr. Day, one of the physicians to the Samaritan Hospital in London, who has given it in between 1200 and 1300 cases without difficulty of any kind. He has reported the interesting fact that twelve drachms is the largest quantity he has ever administered in an operation lasting one hour. This agrees with curious accuracy with the statement made by Dr. Richardson as long ago as 1867, when he reported the quantity used in surgical operations as averaging about one drachm every five minutes. In the case which I saw there was

no apparent period of excitement, the patient coming rapidly under the influence of the anæsthetic and almost as rapidly recovering consciousness. Dr. Day watches particularly the color of the face and the character of the respiration, paying little or no attention to the pulse; although experiments on the lower animals seem to show that when methylene kills it does so by paralyzing equally the circulation and respiration. I have had absolutely no personal experience with this anæsthetic, but am disposed to reject it as somewhat more dangerous than ether, and without sufficient advantages to counterbalance the increased risk.

Nitrous Oxide.—This is made by heating nitrate of ammonium in a retort until it decomposes into watery vapor and the so-called laughing gas. The latter collected in a rubber bag or other proper receiver may then be administered as an anæsthetic by inhalation. It would seem from chemical considerations, nitrous oxide being a stable compound at the temperature of the body, and from experimental observation, dogs dying in it in precisely the same time as when put in nitrogen, that nitrous oxide acts by producing asphyxia, or at least by preventing oxidation of the blood. There is, however, no doubt, a primary effect of specific stimulation of the nerve centres as shown by a period of exhilaration, from which it derives its familiar name. There are a few reported cases of death during, or after the inhalation of nitrous oxide, but, not more than three, I believe, and even these are more or less doubtful. In one of them there was found extensive fatty degeneration of the heart; in another no autopsy was made; and in the third only two inhalations of the gas had been taken when the patient died after the extraction of teeth, probably from syncope produced by nervous shock. In this city at the rooms of certain dental operators enormous numbers of persons (nearly one hundred and forty thousand) have taken the gas without a single death.

The stages produced by this anæsthetic are two: 1. Exhilaration, or the development of the peculiar mental excitement, which is usually cheerful and often boisterously so. 2. Unconsciousness, lasting from two to four minutes, during a portion of which time there is a period of muscular relaxation which is, however, never so complete as under the other anæsthetics. The most common danger associated with the administration of this gas is that arising from a spasm of the muscles leading from the base of the tongue to the hyoid bone and pharynx, producing a condition known as "swallowing the tongue." This sometimes occurs with great suddenness and if unrelieved threatens death from asphyxia. The tongue should of course be immediately drawn forward by forceps and held there until the spasm disappears or the patient recovers consciousness. In cases of extensive heart disease the danger of fatal syncope should be borne in mind, and similarly the risk of asphyxia should be remembered in cases with grave pulmonary troubles. On the whole, however, nitrous oxide may fairly be said to be the safest of all known anæsthetics within the limitation of its present use, which is chiefly in the performance of such trifling operations as the opening of boils, abscesses or felons, the removal of small epitheliomata, the division of fissures of the anus, or the extraction of teeth.

In *résumé* I may formulate the following conclusions:

1. As a rule ether, as the safest of the more powerful anæsthetics, is to be preferred; the lessened risk to life more than counterbalances its minor disadvantages.

2. Chloroform may be employed when ether has failed, or cannot be procured, or when there is a distinct record of serious trouble during a previous etherization. It is possibly safer in children than in adults, and it is said to be exceptionally adapted for administration in obstetrical cases. It has some distinct advantages over ether in cases of stenosis of the larynx or trachea, and may be considered in those cases of emergency in which an operation has to be performed a short time after a solid meal.

As secondary indications for its employment the following may be mentioned:

a. Protracted operations about the mouth, jaws, nose, or pharynx which necessitate the mouth and nose being uncovered.

b. Operations needing the employment of the actual cautery, in the vicinity of the mouth.

c. Severe bronchitis, emphysema, or asthma.

d. Extensive renal disease.

e. Marked atheroma.

3. Nitrous oxide should be employed in operations which can be completed in from two to five minutes.

4. Methylene, methylene ether, and the various anæsthetic mixtures, such as that of alcohol, chloroform and ether, are not so safe as ether alone, and have no decided advantages to compensate for the increased risk.

COMMUNICATIONS.

PRACTICAL ASEPTIC SURGERY.[1]

BY J. W. LONG, M.D.,
RANDLEMAN, N. C.

(*Concluded from p.* 261.)

Having discussed the various prerequisites of modern surgery, and the object of this paper being purely practical, I will now ask you kindly to examine these bags, which you will find contain every thing that aseptic surgery really demands. Take the smaller bag first. You will observe that it is only an ordinary leather satchel, about twelve inches long; that it is carried by the handle or a strap thrown across the shoulder. On opening it, we find a leather strap sewed in loops along the sides, and containing the following articles, to wit: Gerster's iodoform box; a two-ounce bottle of chloroform, with a notched stopper tied to the neck; a two-ounce bottle containing the corrosive sublimate mixture; two ounces of carbolic acid; a half-ounce of Churchill's tincture of iodine—the iodine and acid bottles have a bit of cotton about the mouth and are wrapped in protective; a half-ounce of four per cent. solution of cocaine, and a small pipette; hypodermic syringe, tablets of morphine, and a small exploring-needle; a stiff nail-brush; litmus paper; and two ounces of glycerine, with twine tied around the neck of the bottle for making vaginal tampons. A plain sack or cover made of rubber sheeting about 6 by 8 inches holds one or two ample pieces of protective, a yard or more of corrosive sublimate gauze, and a large piece of borated cotton. In the bottom of the bag is a narrow Esmarch and several cotton bandages. There is also a plain cloth case containing such instruments as one may wish to carry. A little side-pocket holds needles, silk, pins, and safety-pins, the former two wrapped in protective.

This arrangement of the various articles enumerated is very simple and convenient; besides, it leaves the body of the bag for extra instruments, an unusual amount of dressing, or anything else. This bag soon paid for itself over and over again. Now I could not get along without it. With it any minor operation may be done after the style of modern aseptic surgery. I will give some examples by way of illustration.

[1] An address delivered before the Southern Surgical and Gynæcological Association, Dec. 4, 1888.

Case I.—March 1, Mrs. ——, while picking up clothes for the wash, ran a needle deeply into the upper part of the palm of the right hand. It gave her great pain. Her husband immediately telephoned for me, and the operation was conducted as follows: Pulling off my coat and rolling my sleeves above the elbow, I first thoroughly washed my hands and arms in hot water and soap; then I washed the patient's hand and wrist. Next, the instruments needed were laid in a small dish containing a three per cent. solution of carbolic acid—an ordinary goblet will answer every purpose for holding the small instruments necessary in such operations, and two fluid drachms of acid solution to a goblet of water approximates a three per cent. solution. Twenty minims of a four per cent. solution of cocaine were injected into the proposed line of incision. While the cocaine was being absorbed, my hands and the patient's hand and wrist were washed in a 1 to 1000 solution of corrosive sublimate. The application of a rubber bandage rendered the hand and wrist bloodless. A short deep incision was made directly over point of entrance of the needle. The bloodless condition of the parts enabled me to see the needle passing upward and backward beneath the annular ligament, and it was easily extracted. The wound was washed in the sublimate solution, iodoform freely dusted over it, sublimate gauze applied, and snugly held in place by a roller bandage; after which the rubber bandage was removed. The entire operation was painless and bloodless. In a few days, the dressing was removed—the wound had healed by first intention, without a drop of pus. Some one may say that extracting a needle is a trivial matter and not worthy the consideration of this society; but do you think that any one who can not extract a needle aseptically should be trusted to do a laparotomy or a herniotomy?

Case II—Geo. A., about thirty years old, white, had a tumor the size of a marble on the inner side of the left ring-finger. It had been growing four years, since the finger had been hurt in a scuffle. The preparation of hands, patient, and instruments was as in the first case. Cocaine and the bandage were used. A longitudinal incision displayed a dark looking mass, having the appearance of malignancy. The tumor extended through the lower end of the first phalanx and seemed to spring from the medullary canal; the bone had evidently been fractured in the scuffle four years ago. The mass was torn and trimmed out with

forceps and scissors, leaving a healthy looking cavity. This was packed with iodoform gauze, and the whole finger thickly covered with sublimate gauze and absorbent cotton, held in place by a roller bandage. The wound rapidly filled up by granulations, the dressing being changed as often as it became soiled.

Now, kindly notice this larger bag, which is specially gotten up for major operations. It is a leather satchel about 17 inches long, with a stout handle. On the outside are strapped a nest of four oblong tin pans, the inner one holding Dr. Kelly's surgical pad and a piece of rubber sheeting, three by four feet. On opening the satchel you will observe that the partition has a side pocket containing two ample pieces of protective, and several envelopes holding respectively, silver wire, pins and safety pins, silk and needles wrapped in protective; and another containing several powders for making Theirsch's solution. The other side of the partition presents loops for the following articles: razor, shaving brush, nail brush, test tubes, bottle (in tin case) of bone drains, a four ounce bottle (in tin case) of carbolic acid, a two ounce bottle (also in tin case) of Churchill's tincture of iodine, a four ounce bottle of whiskey, bottle of catgut in oil of juniper, a bottle of corrosive sublimate tablets, and a box of iodoform ointment. The body of the bag contains in one side a case (five yards) of corrosive sublimate gauze, an ordinary rubber syringe, a fruit jar holding sponges and rubber drainage tubes in a five per cent. solution of carbolic acid; a four ounce bottle of Squibb's best chloroform protected by a box of wedge-wood; three shallow tin basins; two or three pie pans; two quarter-pound cans of ether; a wide rubber bandage; a cake of soap; and a number of cotton bandages. A fountain syringe to be used as an irrigator is rolled up and placed in the pans. On this side is also a chloroform inhaler, which is simply a wire muzzle covered with coarse cloth. These articles are covered by two or three towels (take plenty of towels with you) all held in place by two transverse straps. The other side of the bag holds a half-pound or more of absorbent cotton rolled in a clean towel. Also an ether inhaler, which is a plain lamp chimney with a soft rubber face-piece. Both inhalers and the fountain syringe are kept in bags of rubber sheeting, as they are apt to get soiled and contaminate other articles in the bag. This leaves a large space for instruments, which are selected for each operation and placed in a cloth case or wrapped in a clean towel and stowed away in the bag just beneath the roll of cotton, which keeps them from jostling about and becoming injured. Some extra towels are in this side also.

Of course the arrangement in the bag of the various articles enumerated is entirely arbitrary and must be made to suit the convenience of each operator. The large bag contains no iodoform, cocaine, hypodermic or exploring needle, and no bandage or scissors, as they are all carried in the small bag; but might easily be added to the large bag.

Case III.—On Feb. 14 I was called by Dr. S. Redding to remove a tumor the size of a large orange from the hepatic region of Miss Hinshaw, white, about 26 years old. The tumor had a history of ten years' duration, and recently had begun to suppurate at its most prominent point. It was causing the patient and family a great deal of uneasiness. We proceeded as follows: A dining-table was covered by a thick quilt and oil-cloth. Upon a small table near by several of the pans shown in the large bag were placed and filled, one with five per cent. carbolic solution for instruments, one with 1 to 1000 sublimate solution for sponges, and two with clear water, one being to drop instruments in as they became bloody, and the other for washing soiled sponges in before being returned to the sublimate solution. A strong sublimate solution coagulates the blood in a sponge and makes it hard to clean; besides the solution soon becomes turbid with blood. Therefore, during an operation, the sponges should be washed first in a vessel containing plain water and then replaced in the sublimate solution before being handed to the operator. An observance of these precautions in regard to the sponges and instruments will prevent confusion and add much to the orderly management of an operation. Another pan contained needles in a three per cent. carbolic solution ready threaded with silk, while another held the dressing—sublimate gauze, iodoform gauze, absorbent cotton, and roller-bandages. The iodoform pepper-box was near; a hypodermic syringe charged with whiskey, and a glass of whiskey were also convenient. Our hands and arms having already been scrubbed in hot water and soap, I proceeded to wash the field of operation, while Dr. Rudding administered ether. After using soap and water on and around the tumor, the parts were sponged with a sublimate solution, 1 to 1000, after which towels soaked in a

similar solution were arranged around the parts to be operated on. A small tub had been placed under the edge of the table to catch the water and blood during the operation, and a large pitcher was filled with 1 to 2000 sublimate solution for irrigation. Every thing being in order, my hands were placed for one minute in a 1 to 1000 sublimate solution, and a bowl of the same placed near by on a chair in which to dip the hands during the operation. The tumor was surrounded by two long elliptical incisions, and rapidly enucleated. Quite a quantity of blood was lost owing to the fact that the tumor, while of a fatty nature, was channeled in every direction with sinuses filled with blood. After the enucleation one or two spurting arteries were tied with very fine silk, the wound irrigated thoroughly from the pitcher, and the sides approximated with numerous silk sutures. The parts then presented a simple straight line of incision about eight inches long. No drainage was employed except a strand or two of silk carried beneath the sutures and projecting from either angle of the wound. While the patient's shoulders were gently raised her back was cleansed of blood and water. Iodoform was freely dusted over the parts, iodoform gauze laid along the line of the incision, sublimate gauze and absorbent cotton thickly applied over this; the dressings were held in place by a wide roller bandage. At the end of two weeks the dressing was removed and the wound found healed throughout, except about an inch in the middle where the sutures had cut out—a retentive suture should have been used. The parts were sweet and healthy, and in a few days were entirely healed.

The dressing employed in this case is a typical example of the dry dressing, and the results of the case—no suppuration and no fever—show what may be expected from aseptic surgery. Below I append a case illustrating the moist dressing.

Case IV.—Dr. W. A. Woollen asked me to see the following case, occurring in his practice. Sam S., black, 7 years old. The patient gave a history of acute inflammation of the right tibia, which commenced last November. Some time before I saw the patient his leg had been lanced for the escape of matter by Dr. Stanton. The left femur was enlarged and tender, but no sinus existed from it. The affected tibia was discharging freely from three or four sinuses, the probe readily detected dead bone. May 2, with the kind assistance of Drs. Woollen, Fox and Walker the following operation was done. The room having been previously scoured—floor, walls and ceiling—and all unnecessary furniture removed, a dining table and a small one were prepared as in Case III; a bed was also prepared. A quantity of boiled water and a number of towels and bowls were provided. The hands of operator and assistants were washed as heretofore described, our coats being first removed and a clean apron pinned around the waist of each. The instruments and dressings and solutions with basins of clear water were arranged as usual. A fountain syringe was filled with 1 to 2000 sublimate solution and suspended from a nail near the ceiling. The edges of oil cloth covering the table were doubled so that the bloody water would be carried to a tub under the edge of the table. The little patient having had a general bath early in the morning was laid on the table and anæsthetized. His leg was thoroughly scrubbed with soap and water, followed by the sublimate solution, 1 to 1000. The limb was elevated to the perpendicular for five minutes to allow the surplus (?) blood to gravitate into the body. It was then surrounded by a sublimate towel and an Esmarch bandage applied from the toes to near the hip; the lower end of the bandage being unwound, the ends were tied in a bow-knot above the knee. This rendered the limb bloodless and should never be omitted in operations upon the extremities, unless positively contraindicated. The operator's hands were again dipped in the sublimate solution and the leg douched from the irrigator. An incision through all the tissues down to the bone and extending from one sinus to another displayed abundant dead bone, pus, and detritus. Thinking to chisel and scoop out the diseased parts and leave a trough of healthy bone, we proceeded cautiously with chisel and gouge. But the further we went the more dead bone we found; finally we discovered that the tibia was honey-combed with dead tissue from joint to joint. This left us with only two alternatives—amputation or exsection of the bone in its entirety. The latter plan was quickly decided upon, in the hopes of giving the little fellow a tolerable limb. The periosteum was easily stripped from the bone and the lower end of the bone broken loose from its attachments, a triangular piece of the lower end adhered to the cartilage and was broken off. In trying to remove this the ankle joint was inadvertently opened, and it was thought best to remove the tibial cartilage in order to insure better drainage.

The upper end of the tibia was loosened from its cartilaginous covering by means of a sharp chisel, and the remnants of bone scraped away with Volkmann's scoop; the knee joint was left intact except an insignificant nick in the synovial sac. During this time a stream from the irrigator had been playing upon the parts every few minutes. The wound, which was very extensive, being again thoroughly irrigated, was snugly packed with iodoform gauze freshly wet in corrosive sublimate solution, 1 to 1000. Over this successive layers of sublimate gauze were laid in an orderly manner, and wet throughout from the irrigator. The entire limb was now enveloped in a thick layer of borated cotton, and this in turn covered by protective extending from the perineum to the tips of the toes. A roller bandage applied rather tightly held the dressing in place and controlled hemorrhage by pressure. Splints were adjusted to insure immobility of the joints and to keep the parts at rest. The last thing was to remove the rubber bandage and see that the blood returned to the toes.

In spite of this terrible operation—compared with which amputation of the parts would have been a comparatively small matter—this child's temperature never reached 102°. His appetite improved and he began gaining flesh almost from the day of the operation. On the ninth day the parts were dressed, using the same precautions as to hands, dressing material, irrigation, etc., as in the operation itself. A little chloroform was given. The wound was found fresh and sweet and rapidly filling up with healthy granulations—"new inflammatory formation" of Billroth. The limb has been dressed once a week since and is now entirely healed, except a short, wide hole at the ankle and the knee.

I show you the tibia removed from my little patient. This case strongly illustrates the triumphs of aseptic surgery. Where is the surgeon who would undertake to save a limb under just such circumstances—after the old ways of surgery?

It may be objected that this paper contains little that is new or original. My answer is, that I do not come with untried theories and impracticable suggestions, but only with those methods proven by actual experience—the only crucible in which the dross is consumed and the gold purified.

—The chemical and pharmaceutical laboratory of the Ohio State University was destroyed by fire Feb. 12.

THE INFLUENCE OF SEXUALISM IN REFLEX OCULAR NEUROSES.

BY GEORGE M. GOULD, M.D.,
PHILADELPHIA.

It has been a matter of frequent observation with me that, prior to the age of puberty, the young, as the result of eye-strain, are troubled a great deal with conjunctival and blepharal congestions and inflammations, and much more than after puberty; that boys, both before and a longer time thereafter, are troubled in this way somewhat more than girls; that girls and women, after puberty, are far more prone to have headaches and neuroses than boys and men. However frequent the exceptions I think the rule is that, with irritational eye-strain, the male sex is more apt to show ocular evidences of the same than the female, that both have these ocular symptoms more before than after puberty, and that after this period girls and women have far more headaches than men. It is a matter of not uncommon observation that vernal conjunctivitis, to which young girls are peculiarly subject is almost incurable, but that it disappears, as if spontaneously, at the age of 13 or 14. Styes are frequently seen in young girls and boys but seldom in young ladies and men. Many other palpebral or conjunctival derangements have been noticed to follow this law. A practitioner of great experience and fine observation, Dr. O. P. Rex, of Philadelphia, tells me he has noted very many such facts in his practice.

I do not at all deny that it is possible to explain certain of these cases as due to some inherited dyscrasia that is conquered by the growth, or whose poison is eliminated by the development of the organism and the power of yet stronger inherited tendencies coming into their destined inheritance of the organism. It may also be said that men often avoid the natural consequences of eye-strain by change of occupation and by freedom from the sewing and the house-life that in women necessitates work at short range. Many other explanations might be found that would satisfy an easy-going logic, but I believe the facts are too numerous and the law too general to be satisfied with such a solution. There must be a more profound law running beneath that will bring the facts into a better consonance with evolution and life.

No student of Wallace and Darwin and the facts of the evolution of form and

beauty both in the animal and the human race, can fail to have been struck with the preponderant influence of sexualism (with its ideals of beauty) upon the life and appearance of all animals and men. To that unconquerable instinct everything, except perpetuation of the species itself, is unhesitatingly and ceaselessly sacrificed. And this is not a whit less true to-day of the social animal, the young man and woman of whatever land or language. My present thesis is therefore this: 1. The natural result of an irritational eye-strain is (in harmony with the physiological law of a return of the reflex to or near the organs primarily irritated) to induce inflammations of the conjunctiva, lids, etc., with the necessarily consequent congestion and despoiling of the beauty of the eyes. 2. To the flowering sexual being, this of all things is most detestable, and all the arts of conscious and unconscious life conspire to prevent it. 3. The methods by which these things are prevented are either (*a*) by means of an inhibition of the return of the eye-strain reflexes to the eyes; or (*b*) by deflecting and derouting the reflex discharges to other organs. In the first case, by withholding, storing and diffusing in the mass of the cerebral centres the incoming irritational stimuli, there is produced the great modern female complaint, headache. In the second case, when inhibition becomes no longer possible, and where, through weak ganglia and irregular associate fibres, the overflow spends itself upon innocent organs, we find the great family of reflex neuroses. It is a matter of great regret that peripheral irritations as a cause of headache are too often ignored, and that reflex neuroses are too often considered as idiopathic affections of the complaining organ.

I have elsewhere tried to emphasize, what is, indeed, sufficiently patent and well-known, that the law of all physiological function is that peripheral stimulus of whatever kind normally results in a reflex or return discharge, motor, vaso-motor, secretory, trophic, etc., to the point, or so as to correspond to, or answer, the peculiarity of the stimulus. Pathology begins when the return discharge is not correspondent to the stimulus. If, by disease of the ganglia, or because of irregularity of commissural fibres, the return discharge is sent by wrong centrifugal routes to innocent organs, we find resulting irritational choreas and reflex neuroses of all kinds. If such reflexes and *débordements* are inhibited, more serious cerebral and mental mischief may result. There are good grounds for believing that headache is often but the first stage or symptom of a hierarchy of functional derangements due to retention and overflow of persisting uncured peripheral irritations. When inhibition begets such tension that *débordement* must take place, it may occur by single or several outlets (choreas, irritabilities, gastric neuroses, etc.); or the discharge may be explosive and general (epilepsies, spasms, etc.); or, again, the outflow may exhaust itself upon intellectual centres and result in monomanias and insanities. It is a good rule of social life and minor morals that a man should, so to speak, burn up his own smoke (extinguish within himself his own personal faults of temper, etc.) without offending his neighbor's nostrils therewith. It would certainly be a great desideratum if the physical brain had the power of neutralizing and consuming those irritational stimuli whose sources it cannot quench. But it seems to have only a limited power of this kind, and the inhibition of irritational stimuli for but a short time results in such surcharge that it is manifested by headache, or in a wretched vicarious overflow upon other organs. We may have toothache in the ear, the stomach, or even in the hip,[1] and eye-strain may be manifest only in the brain, the heart, or the stomach. It is evident that some nervous organizations have more power than others of setting bounds to the unregulated overflow to innocent peripheral organs; some have better smoke-consumers than others. But, in most organizations, the penalty of such power, is headache. All these questions have a dynamic aspect as mathematically exact as thermo-chemistry or gravitation. Give the brain a power of estoping persisting irritational stimuli from their physiological reflexes, and you must supply means of dissipating the inhibited discharges. Such inhibitions and would-be dissipations are the (probably) vaso-motor cerebral disturbances manifested by headache. Intercurrent with the headache there is frequently gastric derangement. It is not clear just what the mechanism of this "sympathy" may be, but there can no longer be any doubt that eye-strain, with headache, may also produce such gastric troubles as dyspepsia, flatulence, emesis, gastralgia, anorexia, etc. Perhaps the gastric irregularity may be an early symptom of the impossibility of longer inhibition and denotes the first relief of tension by this overflow along the line of least resistance. At least,

[1] See, Brubaker, The Reflex Neuroses of Dental Pathology, Lea's American System of Dentistry.

in cases of extreme eye-strain, I have hardly ever failed to find some and often great gastric derangement coexisting with the headache. In other cases this point of weakest resistance is through the motor centres of the extremity-muscles, whence chorea. Should all the gateways present a watchful and firm barrier against the egress, the general tension may perhaps find relief only in that general explosion of many surcharged centres, that goes by the name of epilepsy—after which the brain is drained to a temporary condition of dynamic sanity.

We may now seek an answer to the question, What is the cause of the retention and inhibition of the ocular irritational stimuli, that results in so many evils? It must be a powerful force that can thus reverse the universal law of physiology whereby pain and congestion result in the organ irritated. What is the force that vicariously subjects the brain to injury and headache rather than the offending eyes? Or that, *comme dernier ressort*, will viciously wreak its vengeance upon innocent centers and organs by a reflex neurosis? I can imagine no power or motive strong enough to produce such a preposterous illogicality and injustice, except the all-penetrating and all-powerful one of sexual selection and sexual beauty. To put it brutally, a chemotic and blear-eyed girl would not be the b-aux' favorite, and nature has purchased the clear conjunctiva and limpid beauty of the eye at the frightful expense of headaches and innumerable neuroses. It is no fallacy of sentiment that makes the eye the silently speaking exponent of the soul's deepest thoughts and emotions. To mar its beauty and travesty its expressiveness is a sin against the future and against the species, that deserves and receives nature's most solicitous care. The cerebral centers are compelled to inhibit the reflexes eyeward at whatever cost. The clear-eyed girl chooses, is chosen, marries, and begets clear-eyed daughters—clear-eyed, but, alas! they, all and several, are cephalalgics! If this seem mystical and far-fetched to conservative medical science, it may be urged that our profoundest naturalists and philosophers have not thought similar logic too weak to account for the evolution of the most profound morphological and psychological characteristics of a continental and a cosmic fauna. Before puberty the irritation-reflexes return to the eyes according to physiological law; after puberty, in women almost never, in men perhaps more frequently, but even in men the law is felt, though occupation and a robuster nervous organization prevents the disastrous consequences so often seen in women.

In this sexual factor may be found the chief reason for the fact that ocular strain is by a hundred fold the most fertile source of headache and neurotic disturbance in the otherwise physiologically well-conducted organism. If, according to man's experience, the burthen of love-song and history has been the wound of heart by beauty's eye-glance, the weapon has been two-edged and its polishing has injured the fair possessor quite as frequently as her captive. Add to this the almost equally important fact that eye-strain arises chiefly from subjecting the naturally and normally hyperopic eye to the short-range work demanded of every servant of civilization, and we at once have another potent reason for the astounding frequency of eye-strain. From these two causes we realize why eye-strain is so common, and also why it is so subtilely hidden away under the masks of headache and neuroses. Were still another premise needed for our logic it might be found in the fact of the imperial and transcendant importance, intellectually, emotionally and physically, of the organ of vision above all the other senses, and that disturbances of its mechanism must speedily and intimately injure the coordinations and harmonies of every part of our being.

Why do other peripheral irritations so much less frequently set up headaches and neuroses than eye-strain? For many reasons: Because no other organ is to a thousandth part so intimately bound up with our every act and thought and emotion, and so necessary to them all[1]; because no other organ at the end and completion of its development has unwarned had thrust upon it a strain so unusual and of a kind so wholly different from that experienced in its evolution; because no other organ is so complex, so delicate, so easily thrown out of adjustment; and, lastly and chiefly, because to other organs the reflexes may generally return, according to physiological law, in such a way as to answer the stimulus, without running counter to such a profound

[1] I cannot conceal the thought that, conspiring with the law of sexual selection and beauty there may also have been this of the profound utility and importance of this sense-organ to the welfare of the *individual* organism. Even as a unit (apart from race-instincts) it might be better that other organs, and even the brain itself, should vicariously suffer the punishment of ocular sins, rather than its most important function should be impaired and endangered by the inflammations that would result from the warnings and danger-signals of the properly returned reflexes.

law of the organism as that of sexual selection based upon sexual beauty and perfection.

Next to the eyes, perhaps the teeth are the most frequent source of reflex neuroses. Professor Brubaker's essay contains a highly interesting gathering of such instances. But in the reflex neuroses of dental pathology, the centripetal stimulus seems to be checked and reflected back, or derouted by subordinate ganglia that like the lymphatics act as outposts or advance guards to protect the higher centers from injurious attacks. The intimate and direct cerebral connections of the ocular mechanism render impossible such ganglionic skirmishers and pickets. In childhood, the ear seems to bear the brunt of the derouted dental reflexes, and many a case of deafness is due to impacted or carious teeth. Irregularities of the nasal functions and, to a greater degree, of the genital organs, may occasion cerebral and reflex neurotic phenomena, but far less frequently than those of the eye. All of these, however, are of sufficiently frequent occurrence to put the careful diagnostician upon his guard, and warrant a scrutinizing inquiry where functional derangements do not present their own explanations, do not yield promptly to treatment, and where eye-strain is certainly excluded by the mydriatic examination of a competent person.

These, then, are the practical lessons to be gleaned from the preceding pages:

1. In headache *always* suspect eye-strain, and especially in women in the years between puberty and middle age.

2. In functional gastric derangements, not quickly to be explained otherwise,[1] suspect eye-strain, and especially if headache coexist.[2]

3. In other functional derangements such as chorea, nervous heart, extreme irritability of temper, hysteria, etc., that do not yield to treatment, or that are not idiopathically or otherwise explainable, exhaust the possibility of a reflex neurosis from eye-strain or other peripheral irritation.

4. Have the refraction estimated, under a mydriatic, and the coordination of the external ocular muscles proved, by a scientific authority, *in the case of every child, before or by the age of puberty.*

119 South Seventeenth St.

[1] I have always wondered if Carlyle were ametropic.

[2] I have seen a case in which a monocular rhythmical ptosis lasting for ten days alternating with ten-day periods of persistent emesis, had kept up for two years, the whole due entirely to eye-strain, and disappearing with the relief of the same.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 21, 1889.

The President, Alfred L. Loomis, M.D., in the Chair.

Dr. Charles McBurney read a paper on

The Treatment of Inguinal Hernia with Reference to Radical Cure,

in which he first mentioned a procedure adopted in three cases for radical cure of hernia, and accounted for the return of the tumor by the fact that, in addition to securing a dense cicatrix in the canal, he had failed to remove redundant peritoneum, and thereby to carry out an essential step in the operation, namely, to restore, at the point where the hernia begins, a tense, smooth internal surface of the abdominal wall. It is well known, he said, that in laparotomies where large drainage tubes are used for a considerable period, subsequent appearance of ventral hernia is more likely than where no drainage tube is employed. Where the walls are equally brought together and no drainage tube is used, a smooth, tense peritoneal surface lines the cicatrix, and hernia seldom occurs. In inguinal hernia the loose connective tissue which accompanies the cord and fills the inguinal canal, forms no formidable backing to the peritoneum. Thus to cure hernia radically one must radically remove the predisposing causes, namely, peritoneal laxity at the internal ring, and give sufficient support to the peritoneum at this point.

Having abandoned irritative injections, operators then began to devote most attention to sewing up the external ring with various kinds of sutures, ignoring the fact that a hernia coming down into the canal is quite capable of breaking any suture or cicatrix that might lie before it. Macewen's operation does not reproduce the desired smooth peritoneal surface at the internal ring; besides, the operation is extremely difficult, if not totally impracticable, in many cases. Objections also obtain against other operations referred to. It has seemed to him clear that to reach and operate upon the extreme upper part of the neck of the sac with certainty and safety, the surgeon should expose it fairly, and Dr. McBurney thought he had devised a plan of doing so, but afterward learned that it had been done

years before. When the anterior wall of the canal is split up to and a little beyond the internal ring one can make use of one of two methods: tying with a strong ligature; or cutting away the sac, and sewing the neck neatly and smoothly. In this way it is easy to restore the smooth condition of the peritoneum at the ring. This should now have a backing. Some operators are satisfied to have the support at the external ring, entirely ignoring the canal. This is obtained by sewing together the pillars of the external ring. But such sutures must either give way or cut through the dense pillars of the ring. Other surgeons pass the finger up the canal and trust to more active reparative formation following breaking up of the connective tissue to close the canal directly. Others pass sutures from one side of the canal across to the other, thus endeavoring to narrow it. The only certain measure for obtaining complete closure of the whole inguinal canal, except the portion occupied by the cord, is by the open treatment. But even this is uncertain. To insure firm and dense cicatricial tissue throughout the length and depth of the canal one must carefully pack by some dressing down to the transversalis fascia in the lower, and to the peritoneum in the upper, part of the canal.

Before operating, most careful antiseptic precautions are taken, especially in cleansing surrounding parts. The incision begins a little outside the inguinal ring, and extends sufficiently downward over the sac. This is rapidly deepened over the whole length of the canal, thus freely exposing the aponeurosis of the external oblique muscle. The superficial layers of the sac are now cleared away, and the two pillars are completely exposed the entire length. The sac is still covered below the external ring by fascia, which is now opened. The scissors are pushed under, and the canal is split a little beyond the outer edge of the internal ring. The deeper coverings of the sac are now cut off, this being best and most rapidly accomplished with the fingers. If now the transversalis is removed high up in the canal, it is quite easy to separate the cord from the sac. The cord now being separated from the sac a little within the abdomen, the whole sac is dissected out and lifted up. In some cases, as in congenital hernia, the sac must be cut away from the cord. The sac is now opened, and if intestinal contents are present they are reduced; if omentum, it is ligated, and cut away. Adhesions are broken down if any are exposed. The sac being now held up from the internal ring, the operator inserts one or two fingers through the neck a little way into the peritoneal cavity, to guard positively against return of a piece of omentum or intestine into the sac during the placing of the ligature. The ligature is placed about the neck of the sac at the highest point, the level of the peritoneum, drawn very tightly, and the part cut away. There is then a wound, the upper wall of which is formed by the edges of the skin, superficial fascia, external oblique aponeurosis and conjoined tendon; while the lower wall is formed by skin, superficial fascia, and a strip of aponeurosis or Poupart's ligament, including the outer pillar. The aim being to secure granulation to the bottom, it is not sufficient simply to pack the wound. Stitches are inserted, from four to eight in number, according to the size of the wound, to bind together the tissues which form the upper wall, and two or more tension sutures carried across the wound. The wound is now carefully irrigated, and dusted with iodoform throughout, and iodoform gauze is firmly packed the entire length down to the posterior wall. The scrotal or labial wound is sewed up without packing. Proper dressing is applied to prevent soiling of the wound. The dressing is changed once in four or five days. A clear scar forms in from five to six weeks, and is very strong. The patient is not afterward allowed to wear a truss or support of any kind, as pressure by a truss is regarded as injurious to scar tissue.

Dr. McBurney has done the operation thirty-six times in inguinal hernia. One patient, an old drunkard, died in delirium tremens. In only one has there been a relapse of the hernia, and that can be easily accounted for by a defective operation. The first operation was done only two years ago, consequently the time may not be long enough to convince some that the cure is permanent.

The paper was discussed by Drs. L. A. Stimson, A. G. Gerster, Abbe, McCosh, Hartley, Syms, Gibney, and Murray, most of whom had performed the operation and preferred it to any other.

—The *Journal of the Amer. Med. Association*, Feb. 23, says that the Chief of Police of Berlin has ordered the hospital authorities to note the numbers of the carriages in which patients are taken to the hospitals, and the nature of the diseases of the patients. When the patients are suffering from infectious or contagious diseases the carriages are to be disinfected.

Reports of Clinics.

PHILADELPHIA HOSPITAL.

CLINIC ON DISEASES OF WOMEN—DR. MONTGOMERY.

Dr. Montgomery, in speaking of oöphorectomy for the arrest of growth of uterine fibroids, said the removal of the ovaries and even of the tubes also does not necessarily arrest menstruation. In some women the menopause is delayed one or two years after the removal of these organs.

In diseases such as growths in the uterine walls, in which the menstrual flow is found to be continuing for years after the period at which it would be expected to cease, it is not unreasonable to fear that the removal of the appendages will fail to control the hemorrhages, and a second operation be necessary for removal of the growth. From this standpoint he advises removal of myomatous growths, where it is possible, in preference to oöphorectomy.

Remains of Extra-Uterine Pregnancy.

While upon the subject of abdominal surgery, he related the history of a patient upon whom he had operated a week before. The patient was married, the mother of four children, and had had several abortions from chronic metritis. Dr. Montgomery was called in December, the patient thinking she was again pregnant, and about to abort. She believed herself about five weeks pregnant. She had a free discharge of blood, but there was no enlargement of the uterus and the cervical canal was contracted. The discharge continued for over a week, and was attended with some pain and the throwing off of some membranes resembling decidua. He saw her again in January, when she was complaining of pain in the uterus and rectum, with a return of bloody discharge. Examination now revealed a fluctuating tumor posterior to the uterus, which pushed the uterus forward, and in this tumor could be felt a more solid mass.

The sudden appearance of the mass within a month, the symptoms of pregnancy, the bloody discharge containing decidual membrane, led him to believe an extra-uterine pregnancy present, with the fœtus in active growth. A few applications of electricity were made, but pain continuing and the tumor increasing in size, he was induced to advise operation.

The sac behind the uterus was formed by the matting together of the uterus, ovaries, and broad ligaments. It contained nearly a pint of fluid blood and a firm clot, in which was found some characteristic membrane. The cavity was thoroughly flushed out and both ovaries and tubes removed. These organs were removed, not only because of their being involved in the adhesions of the sac, but for ovarian and uterine distress from which she had been suffering for months. The subsequent progress of the patient had been exceedingly satisfactory.

Retroflexion.

The next patient was a woman forty-two years old, the mother of seven children, who had suffered pain in the pelvis for eight years and since the birth of her last child had menstruated every three weeks. An enlargement was found behind the cervix, which might be due to a number of conditions, viz: pelvic exudation, prolapsed and enlarged ovaries, fibroid tumor, and retroflexed uterus. The presence of exudation, Dr. Montgomery said, might be excluded by the fact that the mass was movable, smooth in outline, and could be readily raised up; that it was not an ovarian enlargement was evident from its close connection with the uterus; it was harder and more dense than would be expected in an ovarian growth, and there was absent the sense of fluctuation, and the marked tenderness characteristic of enlarged ovary.

The fact that the angle existing between the mass and the cervix could be erased by upward pressure against the fundus, and that the uterus could not be outlined by conjoined manipulation confirmed the suspicion of retroflexion of the uterus. If there was any doubt of the condition it might be still further confirmed by the use of the sound. If in spite of the presence of this mass the sound had passed forward in the normal direction and the fundus could be felt through the abdominal walls, it would be an assurance that the retrouterine mass was a fibroid growth. In the present case, however, the sound passed backward.

The uterus is frequently retroverted or retroflexed shortly after parturition, from the pressure upon the heavy organ by a tightly applied bandage. If one is called to a woman suffering from hemorrhage two or three weeks after confinement, let him examine with special reference to the presence of a retro-displacement.

In the treatment of retroflexion, Dr. Montgomery impressed upon the students the fact that the organ is not replaced by means of the pessary. The pessary serves a valuable purpose in retaining or supporting the replaced organ, but it is worse than useless before it has been replaced.

There are three principal methods of replacing the organ. 1. With the fingers. With the patient in the dorsal position, introduce two fingers into the vagina, with the middle finger in the posterior fornix push up the fundus, while the index is placed in front of the vaginal cervix and pushes backward. In this way the organ is acted upon as a lever. 2. With the uterine sound. The instrument is curved to pass the canal, is passed to the fundus, and then its external end moved through an extended arc in order not to injure the uterine membrane, and the fundus is thus carried upward. 3. By the genu-pectoral position and Sims's speculum, in which case we have the influence of gravity. In the latter course, it is usually necessary to draw down upon the cervix to secure replacement.

Now, the pessaries are of value, but a number of considerations are important. First, the pessary must be well adapted to the individual and fit so that its presence can give only comfort. Second, where retroversion or retroflexion has been of long duration it may be necessary to elongate the surface by the pressure of tampons preparatory to the introduction of a pessary. Third, there is a class of cases in which the displacement is redeveloped as soon as the restraining power is removed, in which the wearing of a pessary is very painful. There are cases in which there are bands more or less long between the posterior surface of the uterus and the anterior wall of the rectum. Relief is here obtained only by tearing the rectum from the uterus by introducing two fingers into the rectum above the uterus and dragging the anterior wall down while the uterus is pushed up by the thumb in the vagina.

Dr. Montgomery also spoke of the advantages claimed for electricity by Apostoli and others, who say that the uterus is supported by muscular filament running out between the folds of peritoneum; displacement indicates more or less paralysis of these filaments; hence electricity, through the restoration of the muscular power, holds the organ in position. This treatment has not done accomplished all its enthusiastic advocates claim for it.

As to Alexander's operation, he said that the ligaments become atrophied in marked displacements. The ability to draw them out is frequently restricted by attacks of cellular or peritoneal inflammation, so that the usefulness of the operation must necessarily be limited.

Where patients have suffered long and continually from an obstinate retrodisplacement, the abdominal incision and hysterorraphy seems to be the most feasible method of procedure.

MEDICAL CLINIC—DR. TYSON.

Bright's Disease.

Dr. Tyson introduced the first patient, a German, forty-six years old. He spoke of his having had small pox, scarlet, remittent and typhoid fever, but that he denied having had syphilis. When he came to the Hospital he had swelling in the elbows and wrists, albuminuria and purpuric spots. Three weeks later tube-casts we seen. He was now greatly improved, and, to the unaided senses, his disease would not be apparent. Examination of the urine, however, showed it to be a little turbid from flocculi which had to be filtered out, lest they might conceal a small quantity of albumin. Dr. Tyson said that if filtering does not separate the precipitated alkalies and bacteria, potash could be added and the urine warmed when they would be so thrown down with the phosphates that they could be easily filtered out.

After showing the albumin test and speaking of how acid albumin might not appear, though present, he showed the contact method, overlaying nitric acid with albuminous urine in a narrow tube. He spoke also of the methods with picric acid, for the successful working of which the alkaloids—especially quinine—must be absent. The ferrocyanide of potassium solution does not throw down the alkaloids and is a little more delicate than nitric acid. The mere presence of albumin is not sufficient to establish the presence of Bright's disease, for it might be due to pus or blood. The former is generally visible to the naked eye when in sufficient quantity to give the albumin reaction; the latter may be invisible, so that the microscope must be used to detect it. We may not *find* the casts, and still have Bright's disease; the amount of albumin may also be very small, and we fail to demonstrate its presence. In such a case, if there were no pus or blood corpuscles, we would have to fall back on general symptoms, to detect

the disease. If albumin and casts are present, it means more or less kidney disease; although after a patient has practically recovered a few casts may often be found for awhile.

But the term chronic Bright's disease includes not only the chronic form of parenchymatous inflammations, but also interstitial nephritis producing the chronically contracted kidney, and the amyloid kidney. In chronic parenchymatous inflammations, the tubules are at least the primary seat of attack, though later, the interstitial connective tissue is also involved.

The finding of albumin and typical epithelial casts in the urine, with the presence of dropsical swelling, indicate the existence of acute Bright's disease. Other symptoms are the presence of blood, rendering it smoky, a diminished quantity of urine, and uræmic convulsions or other nervous phenomena dependent on retention of urea and other constituents of the urine.

In the treatment of acute Bright's disease he advised: 1. Rest in bed, which is often sufficient. 2. In the beginning determination of the character and quantity of urine. 3. To act thoroughly on the bowels, after which we will get a better effect from diuretics. 4. Diuretics, of which the best is digitalis, in the shape of the tincture in fifteen drop doses three or four times a day, or the infusion, a half ounce as often; but these large doses are not to be continued long. 5. If the case is very bad, cause sweating by (*a*), hot water cloths and bottles of hot water—a steam bath which is better than (*b*), the dry hot-air bath, which can often be rendered more efficient by slightly wetting the patient first; (*c*), if uræmic convulsions are present hypodermics of one-fourth to a third of a grain of nitrate or hydrochlorate of pilocarpine may be used, and if the patient does not soon sweat, one-fourth of a grain more may be used. 6. In severe cases it is desirable to apply counter irritation to the region over the affected kidneys. Wet cups may be used, and then a flaxseed meal poultice with mustard, the patient being always warmly covered in bed. Even blood letting may be done in convulsions, and in case of convulsions from puerperal nephritis it should always be employed.

—Dr. B. Alexander Randall has been elected Professor of Diseases of the Ear, and Dr. Edward P. Davis Professor of Obstetrics and Diseases of Children in the Philadelphia Polyclinic and College for Graduates in Medicine.

New York Correspondence.

What Prof. W. Gill. Wylie Thinks of Pessaries.—Dr. Bulkley's Clinic.—Annual Address before the Alumni of Bellevue Hospital.—Dr. Carpenter's Treatment of Tapeworm.

New York, Feb. 18, 1889.

Dr. Wylie, Professor of Gynecology in the New York Polyclinic, gave a lecture and clinic on displacements of the uterus on February 14. He considers anterior displacements of little importance; it is usually only in posterior malpositions that treatment is called for. This treatment in his opinion should *never* be by pessaries. In his hospital, for the past several years, he has known only one to be used. They simply support the uterus without reaching the cause of the displacement. Furthermore, they are dangerous, because of their liability to infect the patient. They abrade the mucous lining of the vagina and, opening up the canal, allow free entrance of the air to the abrasion. He has often found women wearing the instruments for months and years without relief, whereas they have been quickly cured by curetting and the use of boroglyceride tampons. The tampons are a favorite method of treatment of many diseased conditions of the vagina and uterus with Prof. Wylie, and he uses them continually to support the uterus in displacements. The tampons are made by cutting sheet borated-cotton into strips, an inch and a half or two inches wide, and rolling them up, with medium firmness, until they are of the desired diameter, preferably about half an inch or a little more. They are then wet with the following:

℞ Boroglyceride . . . . . f℥j
Glycerine . . . . . f℥xiv

Mix and add a saturated solution of alum, containing ℥ss–j of the salt.

Prof. Wylie also thinks Alexander's operation of shortening the round ligaments rarely necessary, for, if the cause of the displacement is treated, the malposition can, in most cases, be cured.

Prof. L. D. Bulkley, at his clinic in New York Hospital, February 13, exhibited a case of leprosy. The patient was a woman, 21 years old, a native of Antigua, West Indies. Her family history revealed nothing, the father having died at the age of 74 and the mother and two brothers are still living and healthy. The patient came to this country three years ago. A year earlier a measly rash had appeared on her body

and, in March, 1886, it was replaced by a papular rash on the arms, hands and scalp, with intense itching. Since then the disease has advanced steadily, until now the face, ears and lips are swollen, white and infiltrated. The voice is husky and the mouth very sore, with fissures on the lips. The arms and forearms are infiltrated and anæsthetic. There is hyperextension of the last two phalanges of the fingers, though the patient sews without difficulty and the sense of feeling is not greatly impaired. The feet and toes are also infiltrated, and there are ulcers and scars on the legs. Dr. Bulkley does not consider the disease contagious, and he cited the case of a priest in a leprous settlement in the Sandwich Islands, who did not contract the disease for seven years and, at last, had his scalp infected by flies. The doctor has had two cases in which he used eucalyptus and chaulmoogra oils, but without effect. This patient not being under his care, no treatment was recommended.

The second patient was a woman 19 years old. She was always well until three years ago, when a small tubercle appeared on the left side of her nose. Since then many more have grown on her face, hands and arms, while the one on her nose has increased to the size of a filbert. The diagnosis, which was confirmed by microscopical examination, was diffuse fibro-sarcoma. Four years ago the patient had an ulcer of the cornea. Iodide of potassium has been used and one growth was scraped, which caused it to disappear. Dr. Bulkley decided to try arseniate of soda by hypodermic injection.

The next patient was a man, 63 years old, who gave the history of being a moderate drinker. When he was 22 years old, his nose began to enlarge and an acne rosacea appeared on it. It developed into a syphilitic process and grew gradually, till now it is exceedingly large and bulbous, red, soft and pulpy to the touch, and the seat of some ulceration. Dr. Bulkley proposed, after thorough syphilitic treatment, to make an incision in the median line, down to the cartilage, scrape away the hypertrophied tissue and removing a wedge-shaped piece. Then by uniting the flaps he expects a respectable-looking nose. The process he diagnosed as rhinophyma.

The annual address, before the Alumni Association of Bellevue Hospital, is to be delivered, in April, by Dr. William Osler. The address will be followed by a banquet.

The late Prof. Wesley M. Carpenter had a favorite treatment for tapeworm, which is as follows: The patient is to eat his breakfast as usual and then eat no more till after delivery of the worm. At 6 A. M., on the second day, he is given Epsom salt ℥j; at 9 A. M., calomel gr. x; at 9.30, decoction of pomegranate f℥vj; at 10.30 A.M. f℥iv of the same, and then "look for the worm." The treatment is perhaps a little severe, but it brings the worm, head and all. The decoction of pomegranate is made by adding eight ounces of the *fresh* bark to one quart of water, and boiling down to ten ounces.

PERISCOPE.

Influence of the Electric Light on the Eyesight.

Dr. Dubinski of Kronstadt has had an opportunity during the last ten years of observing thirty cases of a peculiar ophthalmic affection occurring in young sailors whose duty had obliged them to remain in the vicinity of electric lights. The symptoms of this affection, which he proposes to denominate "photo-electrical ophthalmia" may occur during sleep. The patient is awakened by profuse lachrymation associated with intense peri-orbital pain. Photophobia is extreme. Nothing, however, can be seen upon examination except palpebral œdema and pericorneal injection of a very marked character. With the ophthalmoscope hyperæmia of the papilla is found, and sometimes a venous pulse in the retinal vessels. After a time varying from an hour and a half to three hours these symptoms subside and the patient is able to go to sleep, and the next morning he awakes quite well, with the exception of a certain amount of ocular fatigue such as is caused by reading late at night. Sleep appears to be an indispensable condition for the manifestation of photo-electrical ophthalmia. Thus, in the case of men who have been exposed during the morning to the electric light, when they take a midday nap the disagreeable phenomena wake them up at that time, and not during the succeeding night. Although the patient, when awake, suffers slightly from phosphenes, he is quite able to read and write during the evening. The pathological cause of the symptoms above described would appear to be a hyperæmia of the optic nerve and some lesion of the nervous filaments of the cornea.—*Lancet*, Feb. 9, 1889.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PRESCRIBING OPTICIANS.

The competition between opticians in American cities has grown so keen that the newspapers contain many seductive advertisements, bidding for the trade of individuals suffering with defective vision. Not satisfied with attempts to attract customers by the bait of asserted reductions in prices, many opticians add that at their shops eyes are examined without charge. But this ought not to be. Since ophthalmology has grown into a positive science, it is a grave mistake for opticians to take upon themselves the responsibility of prescribing glasses without the scientific knowledge necessary for this work. Prescribing glasses can only be done correctly with a positive knowledge of the anatomy and physiology of the eye, and day after day oculists are brought into contact with patients who are wearing glasses entirely unfitted for sight. Not only this, but itinerant venders of "crystals" even go so far as to prescribe glasses for headaches, pains, and failing vision, with an assurance that would startle an educated physician. It is within our knowledge that an optician of this city advised a patient, who had been most thoroughly and scientifically examined by a competent oculist, to discard the glasses given by this physician and to wear glasses to which the optician gave a high sounding name, stating that it was not glasses for seeing that he required, but simply "rest glasses."

The observation of careful ophthalmologists indicates that many individuals are given glasses which are worse than useless, and that in some instances so much valuable time is lost that subsequent intelligent treatment is of no avail—some of these are cases in which, if a proper ophthalmoscopic examination had been made and suitable drugs had been prescribed, the patient would have retained vision.

Such a case recently occurred in this city, where a young woman found her vision failing, and, on the advice of her friends, went to an optician, who examined eyes without charge, sold her a pair of glasses, and sent her home with the assurance that all she needed was "rest-glasses." A few weeks passed by, during which her vision grew gradually worse. Another consultation with the optician was held, and another pair of glasses was prescribed. This performance was gone through with twice more, with four changes of glasses in six months; and by this time the patient's vision was reduced to counting fingers at a distance of five feet. At this time an ophthalmoscopic examination revealed the unfortunate fact that the patient has post-neuritic atrophy of both optic nerves. Another case that might be

cited is that of a little girl who was found wearing myopic glasses, given her by an optician, when an examination showed that she was exceedingly far-sighted.

It would not be hard to multiply illustrations of the injurious effects of the practice we have been commenting upon. It does not extend to all opticians; for there are a few honorable exceptions who refuse to furnish glasses when they discover visual defects. But too many dealers in spectacles have no compunctions about usurping the province of ophthalmologists, and yield to the temptations of profit and the unwise solicitations of their customers to do what they have no right to do. In acting thus they sometimes screen the first of these motives behind the second, and affect an air of philanthropy as they exclaim against the high charges of the skilled oculists. But this is a shallow subterfuge; for the charges of oculists vary with the circumstances of patients, and those who cannot pay them can get their eyes examined for nothing if they wish. And, while we may pity the ignorance of persons with defects of vision, who for mere motives of economy prefer to consult dealers in spectacles rather than physicians who make a specialty of treating these defects, we can only condemn these dealers who, knowing the risks their customers run, encourage their error for the sake of gain.

The time will yet come, we hope, when the practice of treating eyes without proper fitness for such delicate work will be punishable by law as other unwarranted assumptions of medical practice are now punishable.

Indeed, we believe that the laws now in force in the State would cover this case, and that a person who could show that his eyes had been maltreated by an optician would have little difficulty in recovering damages. How far the rights of a dealer to sell his wares would protect an optician who combines with his business the custom of examining the eyes and otherwise imitating the regular methods of legally qualified practitioners of medicine, it is hard to say; but it would be interesting to have a test case brought before one of the courts.

DELIVERY OF THE PLACENTA.

Only a few years ago there was a fairly general agreement among obstetricians concerning the proper method of managing the third stage of labor. Nearly all agreed that nature should not be trusted fully in any case, and that art should always be employed in conducting this stage of labor. The method that was in such favor, as is well known, was that of Credé. Of late, quite a change has come about; the teachings of Credé are by no means so universally accepted, and have even been most strongly assailed in the country of their origin.

The methods of placental delivery which have strong champions at this time are: the method of Credé, the expectant method of Ahlfeld, the method of Berry Hart, and the ancient method of traction on the cord.

The method of Credé practically consists in following down the uterus with the hand, placed on the abdomen, as the child is delivered; making gentle friction with the hand to excite the uterus to contraction; during the height of the contractions compressing the uterus, using all gentleness so as to separate and expel the placenta from the uterus; and then to making downward pressure to expel the placenta from the vagina. The placenta may be delivered during the first or second, or not until the tenth pain. According to Lusk delivery is completed by one skilled in the method in from five to ten minutes after the birth of the child. According to Credé the time for expressing the placenta should depend upon the conditions in the individual case; and the operator should have three different objects in view: 1, the removal of existing dangers; 2, the avoidance of threatened

dangers; and 3, the saving of time. The propriety of the first object is universally admitted. The second object is to be accomplished by efforts at expression, as already described. Usually from fifteen to thirty minutes are consumed in the process. There can be no objection to the third object, if in its accomplishment the woman is not injured.

The most prominent opponents of the method of Credé are Ahlfeld, Hart and Charpentier, the objections offered being that it is brutal, that it interferes with the normal mechanism of labor, that it produces increased loss of blood, and that it is the direct cause of the retention of pieces of membrane and placenta. The first objection is founded upon a failure to understand the way in which Credé's method should be carried out. To the second it is difficult to reply, since the nature of the mechanism of the third stage of labor is in dispute, and the evidence supports the view that there are several normal mechanisms. The third objection assumes a result of the method which is contrary to the experience of those who have used it most frequently. The last objection is unquestionably well founded; and it seems safe to assert that a direct relation exists between the percentage of cases of retention, and the rapidity with which the secundines are delivered.

The method of Ahlfeld is called the expectant method, although without entire justification. It consists in attending to bleeding wounds after the birth of the child; and in cleansing, drying, and making comfortable the patient. At intervals of five minutes the cloths applied to the vulva are inspected to see if the discharge of blood is normal. In most cases the cloths need not be changed for one and a half hours *post partum*. Then the urethra is cleansed, the urine is drawn, and the placenta is expressed.

When continuous hemorrhage ensues—not due to injuries—massage is performed. If the hemorrhage is now arrested the expectant method is resumed; but if massage fails to arrest the hemorrhage the placenta is expressed at once.

The semi-expectant method of Ahlfeld does not seem destined to wide adoption. The practitioner loses the guaranty against *post-partum* hemorrhage, which an earlier delivery ensures, and especially the knowledge which is gained by keeping the hand over the uterus until, and for some time after, labor is completed. He also loses the extra time which this plan demands of him.

Hart's method of conducting the third stage of labor is as follows: When the child is born the accoucheur must ascertain that the fundus uteri stands at or below the level of the umbilicus, and that the uterus does not contain a second fœtus. Then an ergotin injection is given in multiparæ, especially if labor has been slow. The cord is not tied until the child cries freely, and then only one ligature is applied, on the placental side of which the cord is cut; the fetal end being allowed to drain thoroughly of its contained blood, after which a second ligature is applied to prevent soiling the bedding. The second ligature must be applied at once in case of twins. Before attending to the cord it should be ascertained by abdominal palpation that the uterus is not so relaxed as to bleed. The hand must be kept over the uterus; nothing is to be done when a good contraction comes on, and the uterus is to be allowed its normal relaxation after the pain is over. Should bleeding from the uterus come on, or the pains be feeble, the uterus must be grasped so as to bring on a contraction and to arrest the hemorrhage. Nothing farther is done in a normal case until the lessening bulk of the uterus shows that the placenta is separated and being expelled; then the expulsion may be aided by expression. One can tell when the placenta is separated but not driven down by noting that gentle expression drives it down.

While not passing upon the theoretical

views upon which this practice is founded, the method appears to have much to recommend it. The hand rests over the uterus, so the practitioner is not appalled at sudden hemorrhage. The uterus is allowed to cast off the secundines—and this appeals to the physiologist. We are as yet however in want of full information regarding the method; more especially in regard to the time required for the natural separation of the secundines. The propriety of using ergot until labor is completed is questionable.

The ancient method of delivering the placenta, by traction on the cord, recently championed by Charpentier, opposed as it is to the natural method of delivery, and having inherent dangers possessed by no other method, must be regarded as obsolescent if not obsolete.

The renewed interest in, and the differences of opinion concerning, the proper management of the third stage of labor should prove instructive. The principal objection which is urged against Credé's method is, that it is too meddling. Many obstetricians who are supposed to accept Credé's teachings practically admit this, for they advocate waiting some fifteen or twenty minutes after the birth of the child before resorting to efforts to deliver the placenta. This may prove to be the solution of the problem. By it the patient is ensured against hemorrhage because the attendant's hand rests on the womb; the uterus is given an opportunity allowed to separate the placenta; and the practitioner's time is not unduly taken.

THE MEDICAL EXAMINER'S BILL.

Some of our readers may have been surprised to hear a rumor that the Faculty of the Jefferson Medical College was opposed to the passage of the Bill to appoint a Board of Medical Examiners which is now before the Legislature of the State of Pennsylvania, and to which we have already referred editorially a number of times. It is pleasant to call attention to the fact that this rumor is incorrect, and that it has been officially denied by the Dean of the Jefferson Medical College, as will be seen by reference to the letter published in the columns for Correspondence in this number of the REPORTER.

We think no respectable medical school in this State could be silent when classed with those who are inimical to this bill, and we hope that the influences which are now said to be working in secret to bring about its defeat may not prove successful on account of any lukewarmness on the part of those who ought to be found among its active and earnest supporters.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

TRANSACTIONS OF THE ROYAL ACADEMY OF MEDICINE IN IRELAND. VOL. VI. EDITED BY WILLIAM THOMSON, M.A., F.R.C.S., General Secretary, Surgeon to the Richmond Hospital, Dublin. 8vo, pp. xxxvi, 482. Dublin: Fannin & Co., 1888.

In the opening pages of this volume we learn that the Academy of Medicine in Ireland has, since its Transactions were last published, asked for and received authority from the Queen of England, to add the word "Royal" to its title; and so this distinguished body has testified its loyalty to the government of Great Britain and received a recognition which is highly prized on the other side of the Atlantic. But it needed no such patent to recommend it to scientific men; for it has long been the source of medical and surgical papers of great value, and its Transactions are equal in scientific worth to those of any medical body in the world.

The present volume fully maintains the standard of its predecessors. It is a matter of regret that the limits of our space forbid a detailed notice of the papers it contains; but we may say that every department of medical science is ably represented in its pages, and that the powers of observation, the skill and the judgment of our Irish *confrères* are abundantly illustrated in it. The volume is a mine of information, and would be a valuable acquisition to any studious physician or surgeon.

LITERARY NOTES.

—B. Westermann & Co. announce the intended publication of an *Internationaler Centralblatt für die Physiologie und Pathologie des Uro-genital-Systems.* There will be one volume a year, issued in about 8 parts, and the list of editors contains the names of some of the most eminent surgeons in Europe.

CORRESPONDENCE.

Treatment of Locomotor Ataxia by Suspension.

To the Editor.

Sir: In the Reporter, February 23, 1889, there is a very interesting and practical editorial on "Treatment of Locomotor Ataxia by Suspension," in which you say: "The method of Motchoukowsky is simply suspension, as usually practised when a plaster jacket is applied for disease or deformity of the spinal column." If it is not asking too great a favor, will you kindly inform me whether the suspension is by the chin and occiput and the armpits, or by the chin and occiput while the patient draws on the rope with his own hands.

Yours truly,

Stanton Allen, M.D.

Brooklyn, New York,
March 2, 1889.

[The suspension is by the chin and occiput and the arm-pits.—Editor of the Reporter.]

The Medical Examiners' Bill and the Jefferson Medical College.

To the Editor.

Sir: The following letter explains itself, and I would be glad if you think it proper to publish it in the Medical and Surgical Reporter.

Yours truly,

Lawrence F. Flick, M.D.

Philadelphia,
March 6, 1889.

Feb. 25, 1889.

Lawrence F. Flick, M.D., Chairman of Committee.

Dear Sir: In reply to your letter of the 18th inst. I beg to state that the rumor of opposition to the medical bill on the part of our faculty is incorrect. We have not considered the matter formally.

The members of our faculty are not opposed to any medical bill that is favored by the general profession of the State.

Respectfully and truly yours,

J. W. Holland, M.D.,
Dean.

—The *Chemist and Druggist,* Feb. 16, states that a statue of Gay-Lussac is to be erected in August, at Limoges, when the French Society for the Advancement of Science is to hold its annual meeting at the date mentioned.

NOTES AND COMMENTS.

Cure of a Case of Leprosy.

In the case reported (*Monatshefte für praktische Dermatologie,* No. 23, 1888) by Dreckmann, the disease was fairly advanced, had lasted four years, and presented numerous nodes, tubercles, and patches of infiltration. There was also marked anæsthesia of the feet, legs, and hands. The mucous membrane was also involved; swelling of the conjunctivæ, a discharging ulcer in the nasal septum, whitish patches on the larynx posteriorly, thickening of the left vocal cord, a small tubercle on the point of the epiglottis, and hard nodular infiltration of both tonsils. The patient, a Brazilian, forty-two years old, was at this time, thin, pale, and weak. The treatment, by means of pyrogallic acid, chrysarobin, and salicylic acid, together with the internal use of ichthyol, as suggested by Unna, was instituted; and finally, in the course of several months, all vestiges of the disease had disappeared, and the patient had grown stout and strong.

The pyrogallic acid was applied mainly to the hands, feet, and legs, in the form of a ten per cent. salve; upon the other parts a salve of chrysarobin, of the same strength; these were applied twice daily. To obstinate nodules and patches of infiltration the same remedies were used in the form of plaster-mulls. To the face a salicylic acid and creasote plaster-mull was applied, once daily. Discrete and sharply circumscribed nodules, when conveniently situated, were excised. The conjunctival swelling disappeared spontaneously. The ulcer in the nose, the nodules on the tonsils, etc., were successfully treated with the actual cautery. The constitutional treatment consisted mainly in the administration of ichthyol, beginning with six grains daily, and gradually increasing to forty-five grains. Under the use of these measures, the writer states, an apparent cure resulted—the general health being restored, and all evidence of the disease dissipated.

As incidental points of interest in the report, may be mentioned that the patient's wife had developed the disease eighteen years before; the wife's brother was also affected. The children, four in number, from fifteen to twenty-one years old, showed no sign of the disease. The patient's parents and six brothers, all living in the same neighborhood, were also healthy.—*American Journal of the Medical Sciences,* March, 1889.

Ignipuncture of the Tonsils.

Dr. Wilhelm Roth, of Fluntern, finds that in order to reduce the size of the tonsils without risk of troublesome hemorrhage, which is not uncommon, especially in young subjects, the best plan is to employ ignipuncture, as has been recommended by Krishaber, and more recently by Verneuil. The tonsils and neighboring parts are first brushed over with a ten to twenty per cent. solution of cocaine. The finest point of the thermo-cautery, heated to redness, is then inserted to a depth of about five millimetres in three or four spots a few millimetres apart from one another on the tonsils. The instrument is not allowed to remain more than one or two seconds in the tissue. The whole operation, including both tonsils, can be performed in a very few minutes without any bleeding, and with scarcely any pain. It must be repeated four or five times at intervals of two or three days, and this is usually sufficient to cause the tonsils to return to their ordinary condition.—*Lancet*, Feb. 16, 1889.

Hysteria in the Russian Army.

According to Dr. Ozeretskofski, of Moscow, the existence of hysteria amongst Russian soldiers is by no means an exceptional occurrence. The affection presents the same diversities of form that it does amongst women. Frequently men suffering from this affection are put down as malingerers. Other cases are looked upon as instances of serious but somewhat obscure organic disease, the true nature of the case being nearly always overlooked, because it is not generally supposed that soldiers are liable to hysteria. So real, however, does Dr. Ozeretskofski consider the existence of this male hysteria, that, having had an opportunity of studying no less than thirty-eight cases in the Moscow Military Hospital, he is convinced that hysteria ought to be recognized as one of the affections which entitle the subject of it to exemption from military service.—*Lancet*, Feb. 16, 1889.

Round Ulcer of the Stomach.

Dr. Cherbakoff, of Moscow, in order to study the conditions under which gastric ulcers occur, injected a solution of chromate of lead into the gastric arteries of dogs, with the result that ulcers were produced which bore a considerable resemblance to ordinary round gastric ulcers in the human subject. These experimental ulcers, however, evinced a great tendency to heal rapidly and completely. This tendency could be combated by increasing the acidity of the gastric juice. Indeed, by this means it was found possible to cause the ulcers to become deeper and deeper until they perforated all the coats of the organ. Clinically speaking, these results would appear to be not devoid of significance, as it is well known that round ulcer of the stomach is frequently associated with hyper-acidity of the gastric juice.—*Lancet*, Feb. 9, 1889.

Iso-Nitroso-Antipyrin.

Reference has already been made in the REPORTER to the alleged toxic effects of the salt (iso-nitroso-antipyrin) which results from the addition of antipyrin to sweet spirit of nitre. Dr. H. C. Wood and Dr. John Marshall have recently investigated the truth of the asserted toxicity of this salt, and they report the results of their investigations in the *Therapeutic Gazette*, Feb. 15, 1889. It was found that the crystals changed in color from green to brown, and developed a very distinct hydrocyanic-acid odor after standing a few hours. The quantity of cyanogen produced in this decomposition, however, is not large, and therefore, they say, could hardly be a cause of serious trouble.

In determining whether the iso-nitroso-antipyrin possesses toxic properties or not, it was administered under various conditions to dogs and rabbits, but in no case, as their experiments show, were the slightest untoward effects observed.

A New Tænicide.

M. Thiel (*Journ. de Méd. de Paris*) has examined the bark of a tree known as the "moussena," the *Acacia anthelmintica* of Baillon, growing principally in Abyssinia, and having a high reputation as a destroyer of tapeworm. It is said to be more active than koussoo, and to have a less disagreeable taste. The bark is the only part of the tree employed medicinally, and this is taken in the form of powder in doses of from one ounce to two ounces, alone, or mixed with honey and stirred up in milk. The Abyssinians mix the powder with flour, and make bread with it, and take a sufficient quantity of the bread with butter or honey three hours before the first meal in the morning. The same evening or the next day the worm is generally expelled in fragments. M. Thiel has found in the bark a substance whose chemical characteristics resemble saponine, and he calls this "moussenine."—*Chemist and Druggist*, Feb. 9, 1889.

Extraction of a Foreign Body from the Uterine Cavity.

At the last meeting of the Imperial Royal Medical Society of Vienna, Dr. Herzfeld reported the following interesting case: On December 30, a woman came into the clinic of Prof. G. Braun, of Vienna, stating that she had washed her vagina in the morning, and that the mouth-piece of the syringe was left behind; vaginal examination showed that no foreign body was present in the vagina. A sound was introduced into the uterine cavity, and the foreign body was then detected. The cervix uteri was dilated, and the foreign body extracted; it proved to be the handle of a crochet-needle. Answering the question as how this foreign body had found its way into the uterine cavity, the woman stated that she was twenty-five years old, and had already been confined of four children. As she did not wish to have more children, she was accustomed, at the instance of her midwife, to wipe her uterine cavity after each sexual intercourse. For this purpose, she used to press down the uterus through the abdominal parietes, and to introduce into it a crochet-needle around which was wrapped a piece of cloth; on one occasion the handle of the needle was left behind in the uterine cavity. Dr. Herzfeld remarked that usually such manipulations are only undertaken for onanistic reasons or for causing abortion; two similar cases had been reported by Prof. M. Hofmann, of Vienna. Such occurrences are important from a medico-legal point of view.—*Medical Press and Circular*, Jan. 30, 1889.

Prize Essays.

The following prizes are offered by the Academia Médico-Quirurgica Espanola: 1. For the Academy Prize: a critical estimate of antiparasitic remedies in medicine, surgery and obstetrics. 2. For the Morales Prize: a critical estimate of lithotrity, lithotomy, litholapaxy, and perineal and suprapubic cystotomy. The Academy Prize is a sum of 250 pesetas (about $50) and the title of Corresponding Fellow; the Morales Prize is a sum of 750 pesetas (about $145), with the same title. Essays may be written in Spanish, Portuguese, French, Italian, English, or German. Fellows of the Academy are excluded from competition. The essays, bearing a motto, and accompanied by a sealed envelope containing the name of the author, should be sent to the President of the Academy, Montera, 22 *bajo*, Madrid, on or before September 15, 1889. Every essay sent in shall remain the property of the Academy.—*British Med. Journal*, Feb. 9, 1889.

International Congress of Dermatology and Syphilography.

An International Congress of Dermatology and Syphilography is announced to take place in Paris, in connection with the Universal International Exhibition of 1889, on August 5 to 10. It will take place in the Museum of the Hôpital Saint Louis. The Presidents are Dr. Ricord and Professor Hardy. Dr. Colcott Fox and Mr. Malcolm Morris are Secretaries for London; Dr. Feulard, Chef de Clinique de la Faculté à l'Hôpital Saint Louis, is the General Secretary. The subscription is 25 francs, which entitles the subscriber to the volume of reports of the Congress. The subjects arranged for discussion are *A* the constitution of the group lichen: 1. Should the denomination of lichen be preserved for a number of affections which modern authors consider to differ one from the other? 2. If not, which affection should be separated; and if a new group of lichens be constituted, what forms should be admitted into it? *B* Pityriasis rubra and generalized primary exfoliating dermatitis: 1. What are the characters proper to pityriasis rubra, and how should those various types be distinguished? 2. Is pityriasis rubra pilaris a species of pityriasis rubra, or a special affection, or a variety of psoriasis? 3. What are the relations between scarlatiniform erythema and generalized primary exfoliating dermatitis? Other questions relate to pemphigus, trichophytic dermatoses, the treatment of syphilis, and the relative frequency of tertiary syphilis. Suggestions are also made as to voluntary papers. Members proposing to take part in the Congress and send communications are requested to communicate with the Secretary before May 15, and to forward a brief summary of their papers. The summary will be printed *in extenso* or in part in the general programme, which will be distributed before the opening of the Congress. This programme, which will be issued at the beginning of the month of July, will contain the names of members who have signified their intention to be present and have paid their subscription before May 15, the order in which they are down to speak on the subjects announced, the order of the day, and promised communications.—*British Med. Journal*, Feb. 9, 1889.

NEWS.

—Dr. Carey A. Evans died in Delphos, Ohio, Feb. 16, at the age of 60 years.

—Dr. H. G. Norton, of Imlaystown, N. J., will remove to Trenton, N. J., about April 1.

—In a suit recently in Boston to recover damages for the extraction of a sound instead of a decayed tooth, the plaintiff has been awarded $150.

—A building on West Forty-third Street, near Fifth Avenue, has been secured for the new academy and library of the New York Academy of Medicine.

—Dr. Loomis, of New York City, has been sued by the widow of the late Dr. Miller to compel him to pay for literary work said to have been done for him by Dr. Miller.

—At a recent meeting in London, presided over by the Lord Mayor, Mr. Algernon Coote suggested a plan for collecting 500,000 pence weekly—about $500,000 annually—to relieve the London Hospitals of debt.

—The Trustees of the William F. Jenks Prize Fund have made arrangements with Messrs. P. Blakiston Son & Co. to publish the successful essay on the "Diagnosis of Extra-Uterine Pregnancy," which, as announced in the REPORTER Feb. 23, has been awarded for this year to Dr. John Strahan, of Belfast, Ireland.

—The Executive Committee of the Medical Society of Virginia has appointed the following physicians to fill vacancies in the Medical Examining Board of Virginia: Drs. James W. Tankard, Dr. Paulus A. Irving, and Dr. Leigh Buckner. The *Virginia Medical Monthly* speaks highly of these men. The physicians whose resignations created the vacancies are Drs. W. W. Douglass, J. Herbert Claiborne, and Oscar Wiley.

—The Philadelphia *Ledger*, Feb. 16, says that the morphine habit has become so prevalent in San Francisco as to give rise to a peculiar slang applying to it and its votaries. The latter are called "morphine fiends," and the process of hypodermic injection is called "taking a shot." Hospital surgeons say that the morphine habit is increasing rapidly, and that most of the victims were initiated in Chinatown. One of these officials estimates that 60 per cent. of the petty offenders sent to the receiving hospitals of the city prison are victims of the morphine habit. Cocaine is so expensive that few acquire the "habit."

HUMOR.

MRS. HAYSEED—So young Wiggins is dead. I wonder what he died of?

Alonzo Hayseed (from college)—I heard it was pulmonary phthisis.

Mrs. H.—Land o'Goshen! and me thinkin' all the time the fellow had the consumption.—*America.*

NOTING a particularly healthy-looking child the other day, a lady asked the nurse, who had it in charge:

"Is that a nursing baby or a bottle baby?"

"Sure it's nayther, Ma'am; it's a condensed milk baby."—*Exchange.*

PHYSICIAN (arousing a tramp one morning from a nap on his doorstep)—Here, what is the matter with you? Can't you move more lively?

Tramp—I'm feeling pretty bad, boss, and can't be expected to move in a hurry.

P.—What's the matter?

T.—I've been at death's door all night.—*Boston Budget.*

A BANGOR lady was very ill a few days ago, and a physician was called, who prescribed for her. The prescription was given to a servant girl, who was directed to take it to a drug store and have it filled. She went to the drug store, but, instead of carrying out her instructions, bought a postage stamp, placed it upon the prescription and dropped it into the post office. In a short time it returned to the physician who gave it. It may be well to add that the lady did not die from the delay in receiving the medicine.

OBITUARY.

D. WILLARD BLISS, M.D.

Dr. D. W. Bliss, of Washington, D.C., died Feb. 21. He had been in poor health for several months, and two days before his death was stricken with paralysis from cerebral hemorrhage. Dr. Bliss was born in Auburn, N. Y., in 1825, and was graduated from the Western Reserve Medical College in 1850. Until the outbreak of the late war he practised medicine in Grand Rapids, Mich. In 1862 he was placed in charge of the Armory Square Hospital, the largest in Washington during the war. It held at times as many as 12,000 to 15,000 soldier patients. In 1865 he resigned this position and engaged in general practice in Washington. Dr. Bliss was present at the death bed of President Lincoln, and, as is well known, was the attending physician during President Garfield's long illness.

THERE IS A PEPSIN

WHICH IS UNIFORMLY ACTIVE, PERMANENT, AND RELIABLE,

IT IS "FAIRCHILD'S."

This Pepsin will not spoil, will not become soft and sticky in the vial, even if left long uncorked.

Fairchild's Pepsin will not "gum up" if dispensed in powders, plain, or with the drugs usually combined with pepsin.

Fairchild's is not a partial peptone, and has none of the well-known characteristics of peptone.

Fairchild's is the pioneer pepsin, it showed the way. It "got there" early.

Its activity has never been exaggerated.

All this time, whilst other manufacturers were still offering the high-dilution saccharated and amylated article, Fairchild's Pepsin was steadily making its way on its merit. Now, no one ventures to ask a hearing for these *placebo-pepsins*.

When physicians now prescribe "pepsin" they mean pepsin—not milk sugar, and pepsin.

All these years, Fairchild's Pepsin was always and everywhere found to do just what was claimed for it—in spite of the attitude, genuine or assumed, which held that all "claims" about pepsin must be taken with a liberal discount.

Every *bona fide* test demonstrated its reliability.

We have never found it necessary to explain or excuse any deficiency or inaction as due to "deteriorated" specimens.

Fairchild's will not disappoint the prescriber under any condition proper for pepsin.

With Such a Record Fairchild's Pepsin is a good one to stand by

FAIRCHILD BROS. & FOSTER,
82 and 84 Fulton St., New York.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

EUPHORBIA PILULIFERA IN ASTHMA.

BY M. GRAHAM TULL, A.M., M.D.,

VISITING PHYSICIAN TO BAPTIST ORPHANAGE, PHILADELPHIA.

In connection with the use of euphorbia pilulifera for asthma I have had the following interesting and instructive experience. I will go somewhat into details with the hope that they may prove of value to the profession.

In the spring of 1888 I was called to attend a man, 55 years old. The patient was a man of means and occupied a position of great trust and responsibility. He was suffering from a severe attack of asthma, brought on in this instance apparently by indiscretion in eating, as it was attended by a severe attack of indigestion. When I saw him he was sitting up in bed, breathing with difficulty, with whistling expiration which could be heard all over the room. He stated that he was subject to such attacks, probably four or five times a year. This one had come on at Atlantic City a few days previous to my visit, and the physician who was called had given him a hypodermic injection of morphine, which had been followed by such severe vomiting that the patient begged me not to repeat it except as a last resort. I then gave him a mixture containing fluid extract of euphorbia pilulifera, potassium iodide, potassium bromide, and tincture of belladonna. I also ordered three drops of amyl nitrite to be taken by inhalation, and that half an ounce of glycerine should be given by injection, as his bowels were very much constipated. I saw him again the following day, and found that he had refused the mixture, after two doses, on account of the intensely disagreeable taste; so that later in the day I found it necessary to give him a hypodermic of morphine gr. ¼, and atropine gr. 1-60. This was followed by the happiest results, the patient dropping into a quiet sleep in about ten minutes.

After this I explained to him the impor-

tance of treatment in the periods between the attacks, ordering him a laxative pill and a stomachic, and telling him to pay special attention to diet and hygiene; and also advised him to spend the following August, when he was liable to an attack, in the mountains.

Although from time to time seeing other members of his family professionally I saw nothing of this patient for some months; but heard indirectly that he desired to see me, as he had been cured of the asthma by the "Buffalo Asthmatic Institute," to which he had been sent by a friend. Finally, about Christmas, I met him, and he at once told me that he had only been waiting a few months to see if his cure held out to tell me about the treatment, and that he now felt he could reasonably feel cured, and that a number of his friends had also been treated with wonderful success in the meanwhile. He cited the case of a cousin who had been unable to lie down for years, but who was now able to sleep in the normal position.

I then went home with him and he showed me the following drugs: The box he had received contained a box of pills, a box of capsules, and three bottles, also a couple of pamphlets with directions, etc. The pills were to keep the bowels regular; the capsules contained quinine (gr. ii) to be taken when catching cold. One of the bottles contained a stomachic to be taken before meals for the avowed purpose of keeping the stomach in good condition; one of the other bottles held the "Asthma Cure," and was to be taken over a period of about two years (with intermissions) in bad cases; in addition to these a thapsia plaster was sometimes ordered.

Upon examining the "Asthma Cure" I was at once convinced that it was the Euphorbia Pilulifera, and taking a sample of it I went over to Mr. Geo. E. Dahis, the druggist who had obtained the euphorbia for me, and without informing him of my reason asked him to compare the sample I had with his fluid extract of euphorbia pilulifera. This he did, and at once pronounced them the same. I then went back to Mr. A. with the two bottles, and he agreed that the taste, smell, and general appearance of the two were identical, except that the fluid extract seemed less clear.

He had been taking thirty drops in a wineglassful of water after meals. He had not recognized it, as I had given it in combination with potassium iodide, potassium bromide, and tincture of belladonna. The third bottle was evidently nitrite of amyl in glycerine. His directions were to take thirty drops at the beginning of an acute attack and not to repeat it but once without consulting the "Institute." The odor was that of amyl nitrite. This in the pamphlet goes by the name of the "clincher."

It happened, oddly enough, that on going home that evening I found a new patient who was suffering from an acute attack of asthma, from which he said, he had suffered since boyhood. This was on Saturday night, and I prescribed fluid extract of euphorbia pilulifera, thirty drops in a wineglassful of water every four hours, telling him to report to me the following Monday evening. I did not see him on Monday, but met him on Tuesday, when he said the reason he had not been around the night before was that the medicine had had such a wonderful effect that he had been able to go to work. The patient told me a month afterward that he had never breathed so freely before in his life. He was a brakeman on the railroad, and was much exposed.

A third patient, a photographer, has given me the same brilliant results since then. I am fully convinced that the euphorbia pilulifera is the key note to the undoubted and remarkable results obtained by the "Buffalo Asthmatic Institute" in the treatment of asthma. Only a few nights ago a friend of large experience in practice told me that one of his own patients was under their care, and that he is now able to sleep in a recumbent posture for the first time in months. My patient tells me the "Institute" has prospered to such a degree that it has opened offices in New York City, and that whenever he goes over he finds the offices filled with patients, and he says they all bear testimony to the wonderful good done them. The head of the affair is Dr. P. Harold Hayes, a graduate, I understand, of one of our leading schools. Now of course he gets his results by natural means, as it is not an age of miracles, and I feel confident that I have indicated above what his specific is.

I have learned that euphorbia pilulifera is a very common weed in Australia, and that it has a great local reputation there in the treatment of asthma and chronic bronchitis. Dr. J. P. Crozer Griffith very kindly sends me the following abstracts connected with the drug. "W. Jayes, in the *Ceylon Med. Jour.*, Aug., 1888, describes the plant known in Sinhaleese as Boordada-Keeriya. The children use the juice to tattoo their arms. The author reports a case of asthma and one of chronic bronchitis, both very obstinate and of long standing, greatly relieved after

a few doses of two fluid ounces of the decoction, taken three times a day. Thomas Christy in 'New Commercial Plants and Drugs' Nos. v and vii, 1888, gives an account of the plant and a history of its introduction into medicine. He says it was first used for asthma and other bronchial affections in Australia. He describes the method of making the decoction. I have now under my care an old lady with chronic bronchitis who is doing wonderfully well upon thirty drops of [the fluid extract of] euphorbia pilulifera, t. d."

I trust that this may be the means of stimulating the profession to using what the above experience has led me to feel may prove a specific for this most troublesome affection.

THE TREATMENT OF CATARRHAL DISEASES OF THE NOSE AND THROAT AT THE UNION DISPENSARY.

BY E. BALDWIN GLEASON, M.D.,
PHILADELPHIA.

Acute coryza is treated by first spraying the nose with "antiseptic solution" until all secretions are removed. The following is the formula for this solution, which has been found superior to Dobel's solution for use in the atomizer as well as for a nose wash for the patient to use at home.

℞	Sodii bicarb.	
	Sodii bibor.	āā ʒ viii
	Sodii benzoat.	
	Sodii salicylat.	āā gr. xx
	Thymol.	
	Eucalyptol	āā gr. x
	Menthol	gr. v
	Ol. gaultheriæ	gtt. vi
	Glycerini	Oz. viiiss
	Alcoholis	Oz. ii
	Aquæ	q. s. ad Oxvi

Several of our Philadelphia druggists have combined the solid ingredients of this formula into a compressed tablet, and, for convenience, these are used at the dispensary instead of the original formula of Dr. Seiler given above. After the nose and throat have been cleansed by spraying with the "antiseptic solution," a pledget of cotton wool saturated with a 4 per cent. solution of cocaine is placed in each nostril; and, after the lapse of a few minutes, the nose is sprayed with a 4 per cent. solution of antipyrin. The effect is to control excessive secretion and the turgescence of the nasal mucous membrane, and this effect lasts, as first pointed out by Dr. Hinkel, for six or eight hours, when the application may be repeated. In this manner, a "cold in the head" may be aborted; or, at least, speedily cured. In very severe cases, however, it has been deemed advisable to administer a saline cathartic as well; and, sometimes, also, small doses of atropia frequently repeated.

Simple chronic nasal catarrh is usually treated at the dispensary by ordering "antiseptic tablets" used at home by the patient as a nose wash, night and morning. Twice or three times a week he is required to present himself for treatment; and, after the nose and throat have been thoroughly sprayed with the antiseptic solution, the following solution is applied through the inferior meatus to the post nasal space by means of a cotton applicator, the parts immediately afterward being sprayed with cosmoline:

℞	Iodi	gr viii
	Potas. iodidi	gr. xxiv
	Glycerini	fʒ ss

If the patient is otherwise in good health, an uncomplicated attack of simple chronic nasal catarrh may get well in six weeks; but the antiseptic tablets must be used for some time longer, and an occasional application of the iodine solution should be made to prevent a relapse.

Hypertrophic nasal catarrh is treated as simple chronic nasal catarrh until the discharge has markedly diminished and all signs of active inflammation have subsided, when the anterior hypertrophies may be burned with the electro-cautery and posterior hypertrophies removed by the Jarvis snare. The preparatory treatment for these operations is deemed essential, as otherwise the reaction from them is very severe and recovery delayed, while the ultimate results are not as good. Antiseptics other than the "antiseptic solution" are now employed. In applying the electro-cautery to an anterior hypertrophy, rather a thick wire is used, made as described in my paper on "Galvano-cautery Electrodes," published in the REPORTER, August 11, 1888, page 174. The cautery knife is carried down through the hypertrophied tissues until the periosteum is reached. If this is not done there will be but little effect from the burn, and the operation will probably have to be repeated to secure a good result. A 4 per cent. solution of cocaine is used as an anæsthetic, because it has been found that, while anæsthesia from a stronger solution appears a little more quickly, yet it is not more thorough, and does not last as long as

that produced by a 4 per cent. solution. Ecchondroses and exostoses of the septum might be classed among the hypertrophies, as they have been proven by Seiler to result from the catarrhal inflammation described by him in a paper published in the *Medical Record*, February 18, 1888. These growths are chiselled off from the septum, Seiler's chisels being used for this purpose. Here again a 4 per cent. solution of cocaine is found to give almost complete local anæsthesia, if it is allowed to remain for some time within the nose on a pledget of cotton. Cocaine has been used very freely in the noses of the dispensary patients operated on, and no untoward effects have ever been observed. I am convinced that many of the cases of so-called cocaine poisoning reported have been simply cases of fainting caused by the shock of the operation, rather than the effects of the cocaine employed as an anæsthetic.

In atrophic nasal catarrh "antiseptic tablets" are prescribed for the patients to use at home, as a wash, two or three times a day, so as to secure perfect cleanliness. As often as possible such patients are seen at the dispensary; and, after all plugs of inspissated mucus have been carefully removed, the following powder is applied by the insufflator:

℞ Argenti nitrat. . . . . gr. v
Amyli . . . . . ʒiiss
M.

This application is followed by a slight smarting sensation, which, however, soon subsides. Should this smarting not occur, the powder is not irritating enough, and its strength should be increased, and as much nitrate of silver as eighteen grains to two and one-half drachms of starch, has been used by insufflation, with the best results. After the application of the nitrate of silver powder, a tightly rolled pledget of cotton is inserted upon the floor of each nostril and allowed to remain there; the patient being instructed to renew it as often as necessary. The silver nitrate probably acts simply as an irritant; but the plug of cotton, by the constant irritation of its presence; not only causes renewed growth of the atrophied parts, but also a watery discharge is at once established, which washes away inspissated and fetid mucus, producing an effect at once noticeable in the changed character of the exhaled air. The cotton, moreover, filling up partly the enormously dilated nares, brings the inspired air more directly in contact with the nasal tissues; so that the nose at once resumes its function of warming and moistening the inspired air, and the chronic laryngitis, usually present in this form of catarrh, gets well almost without treatment. Pharyngitis sicca so soon disappears, probably on account of the increased secretion from the posterior nares, or the altered character of the air breathed; for it is well established that this condition is generally the result of breathing air not sufficiently moist, either through the mouth when the nares are not patulous, or through the enormously dilated nares of atrophic catarrh. There is one patient now at the dispensary, who, with this treatment during the past three months has nearly recovered from rather bad atrophic nasal catarrh; but ordinarily in such cases it takes a year or so to bring about a condition resembling health.

Perhaps the most interesting of all cases are those of ethmoiditis involving the middle turbinated bone. Many stages of this affection may be observed, from a simple polypoid degeneration of the mucous membrane of this region of the nose to large granulations or polypi overlying dead bone; and even in the final stage of cure, in which the dead bone having exfoliated, a large cleft may remain in the middle turbinated bone at the site of the former disease. If the disease is seen in the stage of polypoid degeneration, ethmoiditis is treated at the dispensary by snaring off all redundant mucous membrane from the middle turbinated bone, and by the application of the electro-cautery; when ordinarily the process is checked. When the case is first seen in what might be called the second stage of the disease, and large granulations or polypi are present, underneath which the probe detects dead and exposed bone, the polypi are first removed by means of the Jarvis snare and then the dead bone scraped away with the nasal curette. Ordinarily this is easily accomplished, the dead bone being like so much sand imbedded in soft granulations; but when the probe penetrates deeply before coming in contact with exposed and roughened bone, it has seemed best to introduce a fine electro-cautery knife along the sinus until the dead bone is felt. The cautery knife is then quickly heated. In this manner a slough is produced which brings away the dead bone with it. When polypi are simply snared off, they almost invariably return, but when the ethmoiditis which underlies the whole trouble has been treated and cured, the cause of nasal polypi having been removed

the polypi do not return. No case of nasal polypi is considered cured as long as dead bone can be detected by a fine probe at the spot whence the polyps grew.

Granular pharyngitis, pharyngitis sicca, and chronic pharyngitis being simply the result of nasal disease, get well as the result of treating the nasal trouble; and no applications have been made to the throat at the dispensary in such cases.

Acute tonsillitis is treated by the application of a sixty-grain solution of nitrate of silver to the inflamed structures once or twice a day. A gargle, or still better, a lozenge containing potassium chlorate, chloride of iron and bromide of potash is ordered for the patient to use every two hours. If the patient is seen early this treatment almost invariably aborts the disease. To do good the silver solution must be of the strength of at least sixty grains to the ounce. If a weaker solution is used, its application is painful, but if a sixty-grain solution be employed, there is no pain whatsoever attending its use and the patient immediately experiences a sense of comfort. When seen a few moments after such an application the tonsils no longer appear of a bright red color, but are paler and seem to have shrunken somewhat. Of some thirty cases of acute tonsillitis treated in this way, not one went on to suppuration.

Chronic hypertrophied tonsils are divided into three classes; the soft, the hard, and the ragged. The first, if the anterior pillars are not adherent to them, are removed by the tonsillotome. When adhesion of the pillar is present, however, an attempt should be made to break down the adhesions with a probe and free the anterior pillars from the tonsils; for a branch of the tonsillar artery lies in the anterior pillar which, if wounded, gives rise to troublesome hemorrhage.

Hard, fibrous tonsils also are very apt to bleed profusely when cut, and are, consequently, removed either with the Jarvis snare or by repeated applications of the galvano-cautery, used in the following manner: The cautery knife is introduced cold into a crypt of the tonsil to be removed; and, being heated, is made to burn its way out through the tonsil. As this procedure is entirely painless it is not necessary to use cocaine. From five to ten such applications at intervals of a week are necessary to cause an hypertrophied tonsil to shrink to its normal dimensions: and during the progress of the treatment, little if any pain or inconvenience is experienced by the patient.

The so-called ragged tonsil, whose irregular shape is the result of frequent attacks of tonsillitis and consequent abscesses, is generally treated in the same manner as the hard, fibrous tonsils, unless it is large enough to be grasped by the tonsillotome or snare.

An hypertrophied pharyngeal tonsil and adenoid vegetations have always been removed by the finger-nail of the operator. The patient is seated crosswise on his lap, and the left arm of the operator being drawn tightly about the patient's body, all struggling is prevented. The right hand is now introduced into the patient's mouth and the fore-finger carried behind the palate, when such growths are easily scraped away with the finger-nail, if it be long and strong. As such growths are rare except in children, it has not been found necessary to employ any other method; the oldest case so operated on being that of a young woman sixteen years of age. Adenoid vegetations have also been observed to disappear after removing the fauceal tonsils; and, as the result of frequent applications of the iodine solution to the vault of the pharynx.

REFLEX, OR THE SO-CALLED USELESS, COUGH.

BY STANLEY M. WARD, M.D.,
SCRANTON, PA.

The subject of reflex cough, that is to say, of cough in which, in the words of A. A. Smith, the primary seat of irritation is outside of the respiratory tract, is one that seems to have attracted little attention from writers on medical subjects. In a paper recently read before the New York County Medical Society, Dr. Wm. H. Thomsen (*see* REPORTER, December 15, 1888, p. 750) stated that there are fourteen varieties of useless cough, and among the causes of it he enumerated worms in the intestinal tract, undigested food anywhere along the same canal, the cause of whooping-cough, foreign bodies in the auditory canal, a misplaced uterus, aneurisms in certain localities, and malaria.

During the spring of 1886 there came under my personal observation a typical case of reflex cough. I was satisfied that the cause of the cough was outside the respiratory tract, but to find out just where it was proved extremely difficult. At that time I consulted what literature I had access to, and especially the files of all the prominent medical magazines published in this coun-

try, but with little success except in one instance. A reprint of an article by Dr. A. A. Smith on reflex cough, which appeared in the *American Journal of the Medical Sciences,* came under my notice and was of valuable assistance, especially as it convinced my patient that after all she might not be a victim of "hasty consumption" or pneumonia, as her friends had declared. Dr. Smith in this article narrates the history of eleven patients who came under his own observation, and quotes one from *L'Union Médicale.* As a matter of interest I give an epitome of his cases.

Case I.—Male child, four weeks old. "Began to cough violently, one night, suddenly, and to cry each time he coughed." Had been perfectly healthy. He failed to account for the cough and ordered a teaspoonful of castor oil. Seemed worse next day. A "most careful examination of heart, lungs and throat" failed to reveal a cause for the cough, which continued unaccompanied by fever until the fourth day, when the Doctor had the child stripped to the skin and noticed that every time the child coughed there was an "umbilical protrusion." A compress put over this stopped the cough, but when removed the cough returned. Thus having the key to the trouble the treatment was simple and a compress was fitted over the protrusion, which stopped the cough entirely and completely relieved the child.

Case II.—Female child, two and one-half years old. Always healthy and well until two days before being seen. Symptoms: loss of appetite, some nausea and vomiting, restless at nights, cough and abdominal pain. Examination of heart and lungs negative, but on the posterior wall of the pharynx was "a collection of mucus, and the tonsils were enlarged." Treatment of this condition availed nothing. Two days after the patient was seen with constant cough, temperature 103°, pulse 120, "restless and uneasy." Again a careful examination failed to reveal anything of importance. For three days more the child remained in about the same condition, "despite all my treatment," when on having a movement of the bowels a large peach stone passed in the stool, with a cessation of all bad symptoms.

Case III.—Female child, four years old. Two days before being seen the patient had developed some bad symptoms, prominent among which was cough. She was "anæmic, digestion poor, tongue coated, restless at night." There was no febrile movement. "Thinking I discovered evidences of periodicity in the attacks of coughing I ordered quinia and an anodyne cough mixture." At the end of two weeks there had been no material change. Another examination suggested the possibility of worms in the intestinal canal, and santonin and calomel were given. These had the effect of dislodging an "enormous quantity" of worms, and with their escape the bad symptoms vanished and did not return.

Case IV.—Female child, six years old. Never had been considered a healthy and robust child. "As a baby the patient was subject to attacks of indigestion." During the preceding summer she had been seen by Dr. Smith. The patient then had some peculiar attacks characterized by "pain in the abdomen, distension and diarrhœa, and violent cough and sometimes vomiting." In November she was first seen. For three months before there had been almost constant cough, loss of flesh and appetite, night sweats, pains in the chest, etc. The cough was unaccompanied by expectoration. An examination failed to reveal anything of note. "Treatment availed but little." Two weeks after she came under his care she passed spontaneously several sections of tape-worm. Appropriate treatment was instituted, and the expulsion of the worm was followed by complete cessation of all her disturbances.

Case V.—A woman 25 years old. The patient was first seen in September, 1875. She had had a cough for a month while in the country. Consulted the Doctor immediately on her return. She had been troubled with malarial symptoms the year before, and finding on examination no disease of heart, lungs or throat, he thought this cough might be malarial in its origin. In a month there was no improvement and there were added to the cough these other symptoms: loss of appetite, of flesh and strength, disturbance of digestion, anæmia, headache, and on the left side especially there was thoracic pain. By Nov. 1, all the symptoms were progressing except the cough, which remained "about the same." There was no expectoration. "She had lost since the middle of August about sixteen pounds." Another careful examination of every organ of the body failed to discover the cause of these bad and advancing symptoms. The next day she passed some segments of a tape-worm and treatment therefore with tonics, etc., was followed by such marked improvement that in two

months more she had regained all that she had lost. Dr. Smith remarks in connection with this case that he could not feel convinced that the parasite was the cause of the trouble until he saw the rapid and marked improvement following its removal.

Case VI.—The patient was a woman in whom a cough seemed to take the place of that peculiar condition known as the "vomiting of pregnancy." Instead of having this latter she developed a cough which lasted through two and a half months of her pregnancy and then ceased. This had been noted in two pregnancies, which were all she had had at the date of the observation.

Case VII.—Female child, three and a half years old. The patient was attacked in the early morning with what was supposed to be "croup" by the mother, who knowing the effect that an emetic sometimes produces in this disease administered a teaspoonful of the syrup of ipecac. Prompt emesis followed but the "croupy cough" was seen to depend on the presence of undigested material in the stomach of the child—at least the emetic dislodged a mass of food and among the rest a quantity of meat eaten thirteen hours before, but not a particle digested, and the cough ceased.

Case VIII.—A man forty-five years old, of rather a nervous temperament; a good liver. He had been subject to asthmatic attacks for twenty years. He had a small growth on his back "situated about two inches to the right of the spinous process of the second dorsal vertebra." It was about the size of a split pea, and was not painful to the touch. It was not a neuroma. Scratching this would cause him to cough and to suffer from dyspnœa. This condition could be brought about at any time by stroking or rubbing the growth. The physical signs present on auscultation and percussion of the chest did not change during the time the cough was being forced upon him.

Case IX.—A young woman 19 years old, suffering with "a retroverted uterus and spinal anæmia with all its accompaniments." Electricity was one of the agents used for her relief, and it was noticeable that when one pole was placed on the cervical spine and the other was passed on either side of the spinous processes of the last dorsal and first two lumbar vertebræ she would cough, faintly at first, "but violently if the application were continued." This phenomenon occurred regardless of the kind of current used, but did not happen if either were applied elsewhere than at the points mentioned.

Case X.—A woman, 36 years old, mother of one child. The patient had had a cough for over a year, the cause of which an examination of the chest and throat failed to discover. For three months she was under treatment and though her general condition improved the cough persisted. At the end of this time she made an unusual muscular effort and completely or nearly retroverted her uterus. Her cough at this time is described as being "almost continuously paroxysmal." She also said that at the time of the menstrual flow the cough was aggravated. "An Albert Smith pessary was introduced in a few days, with the effect of . . . entirely curing the cough."

Case XI.—Female child, seventeen months old. After two days of restlessness, loss of appetite, etc., the patient began to cough. There was some febrile movement. She was seen on the morning of the third day by Dr. Smith who, on examining the throat and thoracic viscera, failed to account for the cough. An examination of the gums showed them to be much swollen and "very tender over the upper canines." They were freely lanced and the relief "seemed to be immediate." In a few weeks Dr. Smith was again called to see the child, which presented the same symptoms; this time an examination revealed a similar condition of the *lower* canines, and again an incision relieved the child of the cough.

An analysis of these cases shows that in over fifty per cent. the cause of the reflex cough was at some part of the alimentary tract. The large number of children affected, some with a rise of temperature, and the difficulty which all recognize of examining these little patients satisfactorily, might easily lead some less careful diagnosticians to find cases of pneumonia where a cherry-pit or a tape-worm was in fact the cause of the trouble.

My own case is as follows: The patient, Mrs. L., mother of two children, the youngest still at the breast, was accustomed, in order to increase the flow of milk, to drink two bottles of porter daily, and from a pint to a quart of milk. She had done this when her first child was a nursling and had experienced nothing except benefit. One night during the latter part of April, 1886, she began to cough violently and in paroxysms. The cough was dry and harsh but not "croupy." In spite of

chloral, the bromides, etc., she kept coughing at irregular intervals for nearly twelve hours, when there was a complete cessation for an hour or more. Her temperature was normal. Physical examination of the chest and throat disclosed nothing. She was cheerful and bright and joked considerably about her condition. During the afternoon the cough began again, and with the exception of the times during which she was stupid from the effect of narcotics, it raged with redoubled fury for the next six or eight hours. During the morning of the second day there was a little rest, but it was only momentary. The paroxysms came on and lasted from four to six hours in spite of anodynes freely administered, spraying the throat, blistering the chest, and doing everything that reason or fancy could suggest. Finally, having on the fourth or fifth day exhausted my materia medica, I decided to attack the complaint in another way, and administered a scruple of sulphate of zinc in lukewarm water, and followed it with a half ounce of the syrup of ipecac. I had a rather vague idea that the revulsion which would follow the emesis might have some effect on the cough. After rather longer than usual emesis began, and the stomach ejected mass after mass of coagulated casein. Some of the pieces were several inches in extent and had to be pulled forcibly from the mouth and pharynx to prevent choking. The cough immediately lessened. The patient slept some without hypnotics. The milk and porter were prohibited, and a full dose of pepsin administered, and afterward a brisk cathartic. The patient coughed no more after this except at long intervals, when she would "bark" a little; but practically the cure was complete.

I have no doubt that the cough was produced by the irritation which the undigested casein produced on the gastric filaments of the pneugastric. I do not think the "reflex" cough can be invariably distinguished by its characteristics. Dr. Smith, in the article I have referred to, does not think so. Dr. Thomsen says that is always non-expectorant, and that the sound is always single. It is a question with me whether or not after a variable time the reflex cough may not be so irritant as to set up a pharyngitis and bronchitis with their accompaniments.

—The *Bulletin Médical*, February 27, states that Mlle. Cattani is about to be named *privat-docent* in general pathology in the Faculty of Medicine of the University of Turin.

SECRETION OF MILK FOLLOWING OVARIOTOMY.

BY CHARLES B. PENROSE, PH.D., M.D.,
PHILADELPHIA.

The appearance of the milk secretion following ovariotomy is a rare phenomenon, and one of which I have found no mention in medical literature. It is doubtless a reflex disturbance similar to other well-recognized reflex mammary symptoms, such as pain and swelling, which often accompany diseased conditions of the reproductive organs in women.

The two following cases which have occurred in my experience are of interest in this connection.

Case I.—The patient, M. C., had had four children, but had not been pregnant for seven years. She was operated on for extra-uterine pregnancy, of about ten weeks duration, in February, 1888. The fœtal sac, which was on the left side, was removed along with the ruptured left tube and the ovary. The right appendages, which were diseased, were also removed. Convalescence was slow. Eleven weeks after the operation both breasts became large and painful; the areolæ became dark and swollen; and the secretion of milk appeared, at times so abundantly that it was necessary to milk the breasts in order to obtain relief from pain. This secretion continued without interruption for eight months. Its first appearance corresponded to what would have been about the fifth month of pregnancy if the course of fœtal development had not been interrupted. The woman insisted that she was pregnant for several months after the operation, not only on account of the mammary changes, but also because she recognized other signs, such as morning sickness, which she had had in previous pregnancies. At no time after the operation did she suffer with pelvic pain or any uterine disturbance.

Case II.—The patient, B. S., has never been pregnant. The uterine appendages were removed in December 1888 for left ovarian cyst and double salpingitis. While recovering from anæsthesia she withdrew the glass drainage tube from her abdomen during the inattention of the nurse. The tube was not replaced. Convalescence was uninterrupted. Three days after the operation the breasts became large and painful, and an abundant secretion of milk appeared in them. The patient got up in eighteen days; the secretion of milk, however, continued for two months after the operation.

She has not suffered since the operation with any uterine disturbance. In both the cases reported the milk presented the appearance of the same secretion in a woman at full term.

In the first case it seems possible that the secretion of milk may have been connected with the pregnant state: the cycle of mammary changes continuing, even after the product of conception had ceased to exist. This view is strengthened by the fact that the milk appeared about the same time as in her previous pregnancies, that is, at about the fifth month; and also by the fact that other signs of pregnancy continued to be present for several months after the operation.

In the second case, however, the mammary secretion immediately followed an operation in a non-pregnant woman, and must have been a reflex manifestation caused by the operative interference with the nerve relations of the reproductive organs.

WIRING THE FRAGMENTS IN SIMPLE FRACTURES OF THE LOWER EXTREMITIES.

BY CLAUDE A. DUNDORE, M.D.,
ASHLAND, PA.
ASSISTANT SURGEON STATE HOSPITAL FOR INJURED PERSONS OF THE ANTHRACITE COAL REGIONS OF PENNSYLVANIA.

The subject of wiring in treatment of fractures has been pretty freely debated during late years, and there has been a great deal said against it; but I think its value has been greatly underrated, especially in fractures of the lower extremities. I think there can be no reasonable doubt that in compound fractures of the leg the fragments should be immediately wired, when there is the slightest tendency toward displacement. It decreases the danger which is always present in compound fractures, by giving support to the leg and holding the fragments in good apposition, and in this way causes bony union to take place in a much shorter space of time than when such fractures are treated in the ordinary way.

Every surgeon has seen cases of compound fractures of the leg, which were difficult of reduction and in which the fragments were very often displaced, and consequently had to be brought into apposition again just as often. Now this causes a high degree of inflammation, and a tendency to suppuration if the most thorough antiseptic treatment is not followed, and often even when all antiseptic precautions have been taken. The operation of wiring the fragments obviates these difficulties, and, if it is done carefully, the above mentioned unpleasant symptoms are almost certainly avoided. The inflammation generally abates very rapidly and there is little or no suppuration, if perfect antiseptic treatment is carried out.

But what I particularly desire to advance in this communication is the advisability of cutting down to the fragments in simple fractures of the leg and wiring them. Of course, in fractures in which there is little or no displacement, or when reduction is not difficult, this measure is uncalled for; but there are many cases in which reduction is difficult or impossible, and the number of crippled limbs is the best evidence of it. The fragments are often of such a shape that it is impossible to bring them into apposition or to be able to ascertain what causes the displacement, without laying the seat of fracture open to view. If we do bring the fragments into good apposition we are often at a loss to keep them so, for the ordinary treatment does not prevent displacement. By cutting down to the seat of fracture we are enabled to see exactly what we are about, and after wiring the fragments there can be no displacement.

Dr. Biddle, of the Anthracite Hospital, is an advocate of this method, and the results we have had are the best proofs of its efficacy.

We have a case in the building at present in which Dr. Biddle wired the fragments four weeks ago, and the patient now has a plaster dressing on the leg, and puts his entire weight upon it.

This method is the only one which gives us satisfactory results in fractures of the patella, for there are no other means by which we can get good apposition of the fragments and bony union. All other appliances give us evil results too often for us to adopt them. In cases of fracture of the patella Dr. Biddle cuts down and wires the fragments, dresses the incision antiseptically, and places the limb on the ordinary straight splint with the heel elevated. By the time the first dressing is removed the incision has healed by first intention and we have a simple fracture for treatment, in which we have good apposition.

—The American Association for the Advancement of Science will meet in Toronto, August 27 to September 3.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, February 13, 1889.

The President, W. W. Keen, M.D., in the chair.

Dr. Joseph Price read a paper on

Gonorrhœal Diseases of the Uterine Appendages.

The attitude of numbers of professional men who express either incredulity or absolute disbelief in the causative relation between gonorrhœal disease in women and pyosalpinx and abscess of the ovary, is sufficient justification for a still further discussion of this subject. My views upon the matter are based neither upon theory nor upon microscopic examination. They are from surgical experience only, or from confessions of men whose wives have been diseased by them. From the time that Noeggerath first formulated his belief upon this subject it has been smiled at, contradicted, or controverted, but never in its essentials disproven. In his earlier paper, Noeggerath fell into the common error of enthusiasts, that of attributing too much to his discovery. This, without doubt, led many otherwise fair-minded men to pass over his paper as unworthy of attention, thus impeding the progress that otherwise would have followed its discussion and the observations based upon its claims. In taking up most later surgical works we find the etiology of ovarian and tubal disease considered from this standpoint omitted—a missing link—or differentiated out of sight. This is wrong. As early as 1877, Mr. Lawson Tait and others insisted upon the relation existing between gonorrhœa in man and tubal disease in women. Noeggerath antedated him about five years. Mr. Tait also insisted on its causative relation to perimetritis, this as late as 1883. Schroeder, in the early editions of his *Gynecology*, insisted upon gonorrhœa as bearing a causative relation to ovarian and tubal troubles. In the very latest edition he says: "Gonorrhœa, in the highest degree, appears as a causative disease in women." Sänger also is an ardent advocate of the same belief. He is wrong, however, I am persuaded, in holding that the gonorrhœal infection is always late in revealing its presence in the woman when transmitted by the man. To this subject I shall refer later.

Without further collation of authorities upon this subject, I shall proceed briefly to its discussion. Whether or not the presence of the disease can be diagnosticated absolutely by the presence of the gonococcus of Neisser, is of small importance, if by the chain of common evidence we can connect the presence of one disease with the other in their sequence. If, on discovering tubal disease in a woman who has never aborted nor had any of the diseases incident to childbed, who has been healthy up to a time when vaginitis has occurred, contracted from her husband, after which the woman from time to time experiences increasing pelvic pain, losing strength and weight—the case, it seems to me, is made out, save as quibbling may dispute it. This history occurs in most of the cases I have handled. Of the many cases that have come under my observation, I choose the following as illustrative and typical:

A young married woman, one child. Her recovery from childbed excellent: no gonorrhœal infection of the child at birth. Some months afterward the patient had inflammation of the vulvo-vaginal glands, with suppuration. Later she appeared with the abdomen tense and painful, enlarged tubes and ovaries, tender and painful on the slightest movement or pressure; she had lost in weight and strength. Her husband confessed to the infection of his wife. The diagnosis was made of gonorrhœal pyosalpinx, and operation proved the correctness of the opinion. Both tubes contained pus, were cheesy and friable—the ligatures cutting through all but the vessels. The abdomen was full of fluid, and the intestines gave evidence of acute peritonitis.

The history here is complete, leaving no possible doubt as to the origin of the disease. The early infection here exhibited is at variance with the views of Sänger, and shows that his statements are not necessarily correct, or are accidentally correct, if at all so. There is no sufficient reason why this infection should not be early. I incline to the belief that the disease originates early, but may be slow in its progress, and thus escape attention and discovery.

Dr. J. William White, in opening the discussion, said: I had not intended to take part in the discussion, but as you have kindly asked me, Mr. President, I will say that neither the paper read this evening, nor anything else that I have heard or read, has convinced me of the frequent relation between tubal disease in women and gonorrhœa in men. I believe that such cases as

Dr. Price details are defective in some important point. They assert that the occurrence of suppurative disease of the tubes is a consequence of preëxisting disease in the husband, or of the individual with whom the woman has had connection. It seems to me that by a similar process we could demonstrate the relation between gonorrhœa in the male and mitral disease, cataract, or other ailment in the woman. This is another instance of the *post hoc ergo propter hoc* line of argument. It is carrying a theory, which has an undoubted basis in fact, to great extremes, and, as regards the views of Noeggerath, to ridiculous extremes. His sweeping assertions in regard to the persistence of latent gonorrhœa in the male, and his theory that women having connection with men who had ever had gonorrhœa, are constantly rendered barren, or if they do conceive do so only to abort, and that such women are the constant subjects of ovarian and tubal disease, are, I believe, contradicted by the practical experience of every surgeon and of every general practitioner.

I have had rather exceptional opportunities for examining cases of gonorrhœa in the male. Many of these patients have married, and the majority of them had, and still have, healthy wives and healthy children. While there is undoubtedly some foundation of truth in regard to this matter, and while there are undoubted instances of this form of infection, and while gonorrhœa in the male may produce vaginitis, cervicitis, endocervicitis, and pyosalpinx, yet it seems to me that these occurrences are exceptional, by no means so frequent as is claimed, and certainly not the rule. Dr. Price does not assert his belief in these views, but I am surprised at the favorable tone of his comments upon them. I have always regarded the theories of Noeggerath as examples of the extremities to which an enthusiast may be led, and only to be fitly characterized by the somewhat strong terms of absurd and ridiculous. Certainly in my personal experience I have never seen anything to warrant a belief in the relation of these two conditions, as cause and effect, in any very large proportion of cases.

The pathological side of the subject, to which Dr. Price merely alludes, is, after all, the one of greatest importance. If gonorrhœa in man is, as Noeggerath describes it, latent in a majority of cases, it must be that it depends on a peculiar microörganism, and the invariable association of the gonococcus, or some other low form of animal life, with gonorrhœa, must be demonstrated. In this "latent" gonorrhœa, described by him, there may be no symptoms, and nothing which would enable the practical specialist in venereal diseases to recognize the presence of the affection. There must then be demonstrated at least that some mircrobe is present which belongs to gonorrhœa and produces the disease whenever it develops in the urethra. In order to demonstrate the relation between latent gonorrhœa and these diseases of the tubes and ovaries, some such microörganism should also be found in these latter cases. I believe that in certain persons the nidus for the multiplication of the organism is exceptionally favorable. In such cases it rapidly multiplies and tends to spread, and increases the severity of the disease. These are the cases, I doubt not, in which tubal disease follows infection. That it is frequent, or that there is demonstrated any invariable relation between the existence of the microörganism and such diseases in women, I do not believe has been proven. The clinical relation of the two conditions being, therefore, to my mind at least, not established, and the pathological evidence being entirely wanting, I am compelled to reject as unproven and unfounded the theories which so closely associate an antecedent gonorrhœa in the man with so many forms of disease of the uterine appendages. I believe those theories to have been harmful in their influence upon gynæcological practice in having given apparent justification to a large number of operations, a fair proportion of which I do not doubt will be shown within the next ten years to have been unnecessary and injudicious.

Dr. William S. Stewart: I am much interested in this subject, which is so much agitated at the present day. I am interested in the fact that so many tubes and ovaries are being removed. It seems to me an alarming thing that at the present time this should be the prevailing disease of women. I think, therefore, that it is a matter of great importance that we should come to some pathological determination as to the nature of the contagion of this disease, and whether its prevalence is due entirely to gonorrhœal infection, or to other causes.

I have had some little experience recently in exploring the tubes. I was anxious that some of the specialists who make removal of the tubes and ovaries an every-day matter, should have witnessed the treatment of a case. I succeeded in passing an aluminium applicator through the diseased tube, and in permitting the escape of the pus which the tube contained, and the patient, who I

feared was going to die, recovered. The diminution of the enlarged tube was a matter of great satisfaction to me, as I feared that my previous treatment of the case had been the cause of the development of the disease.

I have passed the probe into the tubes in two other instances, and the results which followed—diminution of the inflammation and liberating the pus—have been a matter of great gratification as well as surprise.

Dr. Hoffmann: Dr. White's remarks show how two persons interested in the same subject may arrive at entirely opposite conclusions. Dr. White has had abundant experience in dealing with these cases, especially in the almshouse, in a class of people where he would be supposed to see the relation between gonorrhœa in the male and certain diseases of the female, especially in the uterine appendages. He, however, fails to connect the two in any marked degree. Bernutz has written a very remarkable work, appearing in the New Sydenham Society publications a few years ago, and the conclusions which he reaches are diametrically opposed to those of Dr. White. Bernutz, in examining 99 cases of pelvic peritonitis in women, concluded that 28 were distinctly attributable to gonorrhœa; 43 were traced to childbirth, and 8 of the childbirths were abortions. If you take away the 43 cases, due probably to infection from some incidental cause, we have remaining 56 cases, of which 28, or 50 per cent., were traced not only theoretically, but by a post-mortem examination, to gonorrhœa, all other causes being eliminated. Taking his statistics of the 28 cases which he considered analogous to orchitis in the male, we have 20 menstrual and 8 traumatic. The causes of traumatism were, in 3, venereal excesses; 2, syphilis of the cervix; 2, the introduction of the sound; and 1, the use of the cold douche during menstruation.

I have myself seen this condition so frequently that I cannot regard it as an unusual accident, and all the less after reading the remarkable record of which I have here a note, can I think that it is accidental. So far as Noeggerath's views are concerned, I think that Dr. Price sounded their value. His views are extreme, and we may as well, now as ever, regard them as extreme. There is no use in laying down the principle that only one cause can produce the disease. The original paper of Bernutz, published in 1857, antedating the publication of Noeggerath, is to me convincing.

Whether or not we always find the gonococcus of Neisser is to me a question of indifference, and not always decisive. We know very well that one microbe will, by its presence, crowd out another. When we open the abdomen and find the tubes filled with stinking pus, in which putrefactive changes have taken place, I am not surprised that the gonococcus is not found, its place being taken by some other form of micrococcus. In such cases I do not believe that the gonococcus is diagnostic.

Dr. White: The statistics of Bernutz and Goupil, to which reference has just been made are quite familiar to me, although it was my impression that they were published in 1861, not 1857. This is quite a different question from the one I was discussing. These were prostitutes of the lowest class undoubtedly infected with gonorrhœa. The proportion of these cases in which pelvic peritonitis occurs is considerable. This is entirely distinct from the cases in which the history of a previous and often a long distant gonorrhœa in the husband is depended upon to explain ovarian and tubal disease in the woman, but in which there is no consecutive history of true gonorrhœal infection of the woman. It is to this that I object, not to the assertion that pelvic peritonitis and pyosalpinx *may* occur in some cases of gonorrhœa, especially in women of the lower classes. Dr. Hoffmann has missed the point of my remarks. I have quoted the statistics of Bernutz in a paper which has been accepted by the *British Medical Journal*, although not yet published. They simply present the records of two of the French hospitals to which the lowest class of French prostitutes are admitted, women broken down in health, and the subjects of virulent forms of gonorrhœa. This is entirely distinct from the proposition of Noeggerath, which connects not only existing disease in the man, but also precedent disease of which all active symptoms may have disappeared, with certain conditions of the woman—barrenness, tendency to abortion, and disease of the uterus and appendages. It is to that I object, and not to the assertion that in a large proportion of cases these complications occur in prostitutes with well-marked gonorrhœal infection.

Dr. M. Price: In regard to the statement of Dr. White that these diseases are more peculiarly connected with these hospitals and these women of low character, I would say that all the cases that I have had in private practice, six or eight in number, have been not only of the better class, but

among the best women of this town. The specimens from one of these cases I should like to show to the Society. This pair of tubes is unquestionably gonorrhœal. I treated the man some ten years ago. I afterward treated his wife for old-fashioned cellulitis and peritonitis. She has had five attacks during the last eight years, in every one of which there was high temperature and quick pulse, with the pelvis filled with inflammatory masses. These inflammatory conditions were cured about as the electrician cures pelvic abscess and pyosalpinx. The health and vigor of the woman were sufficient to cause absorption of the liquid portion of the pus, and for a time the disease was kept in abeyance. Four or five days ago I removed from this woman's pelvis a pint of pus of the most offensive character. This was her last struggle, her last effort to get rid of it. She was unequal to the task, and was slowly dying of a septic condition. The symptoms were of such an urgent character, that I opened the abdomen and removed both tubes. There we have a marked case of pyosalpinx unquestionably of gonorrhœal origin. Out of the eight or nine cases of pelvic trouble, I have had occasion to operate on, in all but one I could distinctly trace a gonorrhœal origin. In every one I had treated the man for gonorrhœa. From that day not one of these women bore a child. They always complained of symptoms of pelvic trouble, pain on pressure, pain on movement, and pain on slipping or jarring. The trouble in these cases was just as certainly gonorrhœal in origin as that any trouble existed.

The cases that Dr. Hoffmann has referred to as occurring after labor, have, I believe, in many instances a positive gonorrhœal origin. I recall one case of abortion where there was for a year previous unquestionable evidences of tubal trouble on one side. The abortion was followed by acute tubal inflammation, sepsis, and death. An attempt was made to relieve her, but it was too late. My impression is that a perfectly healthy woman, who has never been inoculated with gonorrhœal poison, is very slow to take on pelvic inflammatory trouble. It probably does exist, but there is usually a poison which has produced the condition, which these other incidental accidents aid and help.

Dr. White: I should like to ask Dr. Price what symptoms of gonorrhœa these women presented in addition to those which he has mentioned. To my mind, the argument, as I said before, seems to be entirely of the *post hoc ergo propter hoc* style, and it would apply just as well to a series of cases of goitre. It would not be difficult in a large number of these cases occurring in the best society, to demonstrate that ten years previously their husbands had gonorrhœa, but it is evident that in both series of cases there would be a missing link in the chain of evidence.

Dr. Price: A man comes to me stating that he is in trouble, and that he fears that his wife has been inoculated. I treat the husband for unquestioned gonorrhœa. In the course of ten days or two weeks, I treat the wife for unquestioned gonorrhœa. I think that is sufficient evidence as to the cause. I do not see any relevancy in the reference to goitre or heart disease. We know why these come in some instances. It is as plain to me as the nose on Dr. White's face that these conditions come from gonorrhœa, and from no other cause.

Dr. James Collins: I wish to ask one question. I have seen something of practice in my life, and I should like to hear something said with reference to the proportion of cases in which this trouble occurs. Taking the cases of gonorrhœa in men, I should like to know in what proportion of cases these sequelæ occur?

Dr. Hoffmann: I do not wish to cross fire; but it seems to me that as Dr. White has suggested that I have missed the point of his remarks, I might say that he has missed the point of what I said. I do not absolutely accept Noeggerath's views, which I consider extreme. I do not believe that a man who has once had gonorrhœa and has been completely cured, will necessarily transmit the disease. Dr. Price did not advocate that view. The only question is this: whether or not in the absence of any other proven cause, such as abortion, exposure to cold, the introduction of the sound, or the like, and gonorrhœal infection proven, the disease may be caused by the gonorrhœa? I think that when that is proven by experience with low-grade prostitutes with the same anatomy and physiology as the high-born ladies, we may apply our experience with the former to the latter. The whole thing is, therefore, narrowed down to this: whether or not we are justified by the exclusion of all other causes in saying that gonorrhœa is the cause. This brings us to a rational consideration of the question, and not the extreme views suggested by Noeggerath. The trouble is that in considering these matters men are apt to go to extremes, and to say that one condi-

tion or another is the invariable cause of the disease. I have seen tubal disease come from all the causes enumerated by Bernutz. The treatment of the disease must of course modify the condition as propagated from one sex to the other.

Dr. J. M. Baldy: The views of Noeggerath, Burnutz, Sinclair, and others, including the author of the paper of to-night, are very extreme, and grossly misrepresent the facts. Venereal disorders in man are not so frequently the cause of pelvic inflammatory diseases in women as these men would have us believe. I think with Dr. White, that in order to settle this question, we must have more than mere clinical evidence; we must also have pathological research and experimentation. So far as the clinical aspect of these cases is concerned, I may say that the vast majority of them coming under my observation are not women who have never been pregnant. There is almost always a history of abortion or labor, with septic trouble at that time. Sinclair has demonstrated that most of these patients have the gonococcus present in the secretions of the vagina and uterus, and for that reason he has considered the disease to be of specific origin; in some cases where the gonococcus was not found he still believed the disease to be of specific origin, supposing that the gonococcus had been crowded out by other forms of micrococci.

The question arises whether the gonococcus causes gonorrhœa. I think that it has been positively settled by the experiments of Sternberg that the gonococcus is not the cause of gonorrhœa, and that it may exist in other discharges. He made pure cultures of the gonococcus and inoculated the eyes of animals with negative results. The vaginæ of animals were inoculated with these cultures, with the same result. He then secured three hospital patients who were under observation in bed, and inoculated the urethras of these men with the pure culture of gonococcus. The results were absolutely negative. The only observations opposed to this are those of Bokard, made at Buda Pest. He submitted the urethras of half a dozen medical students to experimentation. At the end of a week three of the students were found to have well-marked gonorrhœa. At first sight these experiments seem as conclusive as Sternberg's; but when we recall the fact, that these patients were medical students, and had a week's liberty before and after inoculation, in a city with the moral tone of Buda Pest, the experiment is absolutely worthless.

Sternberg found a microörganism in urine which had undergone alkaline decomposition so like the gonococcus that the two could not be differentiated. He has also found it in the pus taken directly from a whitlow. I think that in view of these observations, we can consider that it is proven conclusively, that the gonococcus is not the cause of gonorrhœa, and therefore whether the gonococcus is present or not, it makes little difference; its presence is not proof that the condition is due to gonorrhœa. In accepting this view we can plainly see that the conclusions drawn by Martin, Sänger, and other Germans, from the presence of gonococcus, are erroneous.

In regard to cases of chronic gonorrhœa or gleet, where, following gonorrhœa, there has been a stricture for years, with a little discharge, either mucous or pus, observed in the morning: such cases will no more cause gonorrhœa than will the gonococcus. Up to the present time no experiments have been made on this subject. I am at present engaged in investigating this matter, but am not yet ready to give the final results, as my observations are not yet completed. I will, however, say this: I have taken the discharge from the cases that I have mentioned, and inoculated the eyes of rabbits, with entirely negative results. Not satisfied with taking these discharges, when the urethra was in a quiescent state, I have irritated the parts by the passage of sounds two sizes larger than the men had been accustomed to use, and the next morning inoculated the eyes of rabbits, but still with negative results. Then fearing the criticism that Sternberg did, that possibly animals were not susceptible to this infection, I secured a man and inoculated his urethra with this discharge, and so far with just as absolutely negative results. If we prove that these cases of gleet and chronic gonorrhœa will not cause gonorrhœa, that the gonococcus will not cause gonorrhœa, and that the gonococcus is found in other discharges as well, we come down simply to the acute cases of clap as the cause of these pelvic inflammatory diseases in women. This is exactly where we stand. That a man with acute gonorrhœa will inoculate a woman is beyond peradventure true, and that the inflammation so set up will travel along the mucous membrane of the vagina, uterus, and Fallopian tubes, causing pelvic inflammatory trouble, is beyond cavil. That we can prove more than this I think is impossible. Pathological research and experimental investigation are against it. There remains nothing but the clinical facts. And

here again we have illustrated how two different minds will approach a subject from the same standpoint, and yet draw different conclusions. In many of the cases in which I have seen Dr. Price draw the conclusion that the trouble was due to gonorrhœa, I could find no proof of that fact to satisfy my own mind. To me the history of gonorrhœa was most eminently unsatisfactory, while the history of puerperal septic infection, which he chose to ignore altogether, was perfectly plain and clear. I think that in many of these cases of pelvic inflammatory trouble, the origin is of a septic character, puerperal, or from dirty instruments. I should say that three-fifths of the cases that have come under my observation, were of septic origin, and that one-fifth was of gonorrhœal origin, leaving one-fifth for all the other causes.

Dr. George Strawbridge: Are we to understand that the inoculation of mucous membranes with gonorrhœal pus is negative?

Dr. Baldy: No, sir. I refer to the discharge from gleet, where the discharge has been present for years. Such discharges produce no effect when inoculated.

Dr. Strawbridge: Some of the worst cases of conjunctivitis that I have seen have been due to the inoculation from chronic gleet. In some of these cases the entire eyeball has been destroyed in the course of forty-eight hours. In these cases the acute attack had passed over one or two months before. I have seen dozens of such cases in my own practice. I am quite amazed that the gentleman could use this pus without trouble following.

Dr. White: I think that Dr. Baldy and Dr. Strawbridge are talking about different conditions. I have never seen gonorrhœal conjunctivitis from gleet. The cases seen by Dr. Strawbridge have been in the later stages of acute gonorrhœa. He speaks of one or two months. Gonorrhœa will often retain its infective properties for that length of time. Gleets, depending as they commonly do on strictures of large calibre and on catarrhal conditions of the mucous membrane, are attended by discharges largely mucoid in character, only under exceptional circumstances mucopurulent, and are not contagious except in rare instances. A creamy or milky discharge is apt to be infectious, while a mucoid discharge is, as a rule, innocuous.

Dr. Arthur V. Meigs: I wish to say a few words bearing upon the purely pathological side of the question. As yet I have only made a thorough examination of two specimens, and these were given me by Dr. Penrose. In neither was there what could properly be termed pyosalpinx. In one there was no trace of pus, but extensive inflammation and thickening of both tube and ovary, with adhesion of the tube to the ovary. In the other specimen there was a pocket of pus extending from the fimbriated extremity of the tube, its other attachment having been broken in the removal. There was, however, no pus within the tube, but as in the other case thickening, inflammation and adhesions. I think that it is still an open question whether or no nature could remove such a degree of inflammation as was present in the first specimen, though there is every reason to believe that nothing but operation could have removed the adhesions.

Dr. Price: I am not surprised that Dr. Strawbridge is amazed at Dr. Baldy's remarks. At the present time we are in possession of sufficient clinical evidence to prove what Dr. Strawbridge has said in regard to the causal relation between gonorrhœa and gonorrhœal ophthalmia. Years ago Dr. Agnew said that he dreaded to see a case of chronic gleet of two weeks' or two years' standing come to his office; and it is just these cases that can destroy the eye. The records of eye hospitals abundantly prove this.

We now care nothing, or next to nothing, about what Noeggerath wrote, for we possess sufficient clinical material in our own surgical experience to prove that gonorrhœa, and nothing but gonorrhœa, is responsible, except in rare instances, for the pathological conditions with which we surgically daily deal. Dr. Deaver and Dr. White have proven this in their own daily experience by sections for pus tubes due to gonorrhœa.

Dr. Baldy has alluded to my cases, but he heard only the history of the patient in front of him; but in every case, I subsequently obtained the history of gonorrhœa and stricture from the husband. The question of the influence of gonorrhœa in the production of pelvic diseases in women is one not necessarily dogmatic nor mathematical, but involving probabilities. As to the influence of this disease in producing a serious train of sequelæ in men, there seems to be no dispute; why there should be such a disparity between cause and effect with only sex to influence the condition, is a question that I do not believe the sceptics will attempt to explain. I have certainly no explanation for gratuitous disposition.

In the class of patients met at the almshouse, among the men there is no question

as to the great prevalence of gonorrhœa. Among the women it exists about as often. In his description of a case, in the MEDICAL AND SURGICAL REPORTER, December 15, 1888, Dr. White says: "Two small patches of ulceration existed on the floor of the membranous urethra, each measuring about two lines in diameter." This case may be taken as a type of the many cases of which no microscopical examination can be made, or at least is made. Further on in this same paper, a troublesome case of gleet is noticed, having existed for several years. That the presence of gleet is a real source of infection is no longer doubted. Why then dispute that an existing cause of trouble must stop short and lose its virulence as soon as it touches the female organs? Among the complications of gonorrhœa in men, noted and admitted by good authorities, are peritonitis, subperitoneal abscess, perinephritic abscess, together with the only too frequent lesions of the bladder, prostate, and kidneys. Now, if peritonitis can occur with gonorrhœal origin through the roundabout road of the vasæ deferentes and seminal vesicles, how much more likely is it to occur in women by the direct route from the vagina, through the uterus and Fallopian tubes to the peritoneal cavity? Sinclair, in his little book, faulty and full of shortcomings as it is, proves without doubt that most of the cases of pelvic peritonitis attributed by him to gonorrhœa are rightly so ascribed. Out of fourteen cases cited, in three the diagnosis is not proven and may be regarded as doubtful. It is the danger of every enthusiast to see too much in his theory. This was the cause of the slow reception of the theory advanced by Noeggerath. Noeggerath's view is not a new one; it is only the wide application that causes it to differ from opinions held long before. I can readily understand why the profession should be practically ignorant of the ravages of this disease. Nothing short of a rigid special training will enlighten the profession in this field. Again, it is additionally strange that in this age of boasted progress the profession should question the great prevalence of gonorrhœa in women, knowing it to be so very common in men.

Many important investigations have been made by Bumm, Sänger, and Oppenheimer. Donné, in 1844, discovered a parasite in the urethral discharges which he named trichomonas vaginalis. It is folly here to allude to the numerous small beasts that have been found in genital discharges—forerunners of Neisser's gonococcus. The latter presented his researches just at a time when the world was prepared to accept anything in the shape of a small beast. Clinically it is not necessary to determine the presence of the gonococcus to establish the infective virulence of gonorrhœal pus, and this I believe is in accord with the many researches on the subject. Considering it from a pathological and surgical point of view, a clear history of recent impure sexual contact, in the presence of certain well-known clinical features, ignoring the presence or absence of the gonococcus, will be accepted as sufficient evidence of the vice, and responsible for a large number of grave pelvic diseases, a much larger number than puerperal fever or syphilis is responsible for.

I think that I could easily prove my position by using the clinical evidence from my own college mates. I have taken pains to look them up, and investigated their histories, that I might draw some conclusions in that way. I think that I can prove a causal relation in that way, having personal knowledge of their contamination.

REPORTS OF CLINICS.

UNIVERSITY HOSPITAL.

GYNECOLOGICAL CLINIC—PROF. GOODELL.

Case of Oöphorectomy.

The patient was a woman thirty-eight years old who had been married nineteen years, during which time she had had seven children. Three years ago she had a miscarriage, followed by a septic fever keeping her in bed seven weeks; since then she had had pain in both groins, especially in the left, walked with pain, and could not work. Besides she has had a leucorrhœa appearing in gushes, which points to tubal disease.

Dr. Goodell said that the patient had an enlarged left ovary and tube, and as she was in pain all the time, and wholly disabled, he felt justified in operating. He stated further that since he had begun the new departure of performing all the laparotomies in the crowded amphitheatre, there had been over a dozen in all with but a single case of septicemia, and that in a woman with two exceedingly offensive and purulent cysts which were universally adherent.

Making a longer incision than usual on account of the large amount of fat, in the abdominal walls, he cut between the recti muscles. After tearing apart the preperitoneal fat, and after pinching up a fold of peritoneum to feel whether it had omental or

intestinal adhesions, he raised it up by two catch-forceps and divided it between them. Upon the right ovary was found a corpus luteum. The Fallopian tube, which was occluded and thickened, was, together with the ovary, divided just above the ligature, which had been applied as near the uterus as possible, by the Tait knot. The left ovary, unlike the right, had adhesions which had to be broken up. It was doubled up under the broad ligament, and had to be unfolded. Dr. Goodell put in a sponge before dividing its attachments so as to collect any blood, and then, after ligating, removed it and the left Fallopian tube, also as close to the uterus as possible. The cavity was syringed out with warm *water* which had been boiled; and as it came out clear, no drainage tube was introduced.

Dr. Goodell remarked that he used the following method for cleansing sponges: They were washed, taken home and put in running water for a night; then soaked for twenty-four or forty-eight hours in a solution of washing soda (℥j to a pound of water) which is better than sulphurous acid, as it does not injure the sponges, although it discolors them. They are then, after being rinsed, put in a five per cent. solution of carbolic acid in water. By this process he is enabled to use them over and over again, and he prefers them to new ones. When a sponge has been used in pus cases, and has become saturated with purulent matter, he does not use it again for abdominal work, but reserves it for cases of cancer of the cervix.

After counting the sponges and instruments which had been used in the operation, the wound was dressed with the iodoform dressing, which he directed should remain on for a week.

The Danger of the Forceps.

The second patient he showed was a woman upon whom he had operated in the amphitheatre three weeks before by his own method, for a bad tear through the recto-vaginal septum. It extended one and a half inches up, leaving her wholly unable to control the sphincter. The patient was ready to leave the Hospital in a week, the operation having proved a success. The tear had followed the use of the forceps, and the reasons why he brought the patient before the class were to show the result of the operation which they had witnessed, and to impress upon them, that as young men who had not attained the requisite skill which long years of practice alone gives, they should remove the forceps as soon as the perineum is well distended by the head, and should leave the subsequent delivery to nature. For otherwise they would be liable to turn out the head too soon, that is to say, before the parts had become sufficiently dilated. In his experience he had found that fully nine-tenths of all complete tears of the perineum were due to the use, or rather to the misuse, of the forceps.

SURGICAL CLINIC—PROF. D. HAYES AGNEW.

Hip Joint Disease.

The patient which I introduce is a girl four years old, and is a pale delicate child. Sometime back, her mother noticed that she had a very distinct limp when walking, always growing worse toward evening, and less noticeable in the morning after a night's rest. Recently, however, her nights have been passed with much less comfort, her sleep being interrupted by spasmodic starts of the affected limb. In order to examine the joint I shall place the patient on the table, the object being to ascertain the mobility of the articulations. When the affected limb is adducted and abducted the pelvis is seen to move with the leg. When the leg is flexed on the thigh and the thigh upon the abdomen, the same effect on the pelvis is produced, as seen in the raising of the buttock. When similar movements are made on the sound side the pelvis remains unmoved. In this fixedness of the articulation, we see nature's attempt to immobilize the joint, a most suggestive fact to guide the surgeon in the treatment of coxalgia. Pursuing the examination further, I next ask you to look at the change which has taken place in the buttock of the affected side. It has lost its normal rotundity; is lower than its fellow of the opposite side, and passes into the femoral region, with no sharp defining line, in striking contrast with the gluteal mass on the sound side where the boundary between the two is marked by a deep crease. Let the child now stand up and you will observe something peculiar in her attitude. The entire weight of the body is seen to rest on the sound limb, while the diseased limb is advanced, slightly flexed at the knee and somewhat rotated outward. No pain, I believe, is complained of at the knee, though this symptom is often present. The case, therefore, is a plain one, admitting of no uncertain diagnosis. It is a typical instance of coxalgia, or hip disease, in its first stage.

The seat of this form of articular disease is located in a large number of cases

in the superior epiphysis of the femur—an epiphysitis, and has a tubercular origin. The treatment consists first in fixation of the joint, in order to lessen the blood supply, and thus combat the inflammatory element of the disease; and second to relieve the muscles of a very irksome duty, that of immobilizing the articulation—both important antiphlogistic measures. These ends may be accomplished by placing the patient on the back and applying extension to the limb in the way we treat fractures of the thigh; or, if the child is old enough to use crutches, by placing my modification of Thomas's splint to the posterior part of the pelvis and limb, elevating the sound leg by means of a high shoe, and then allowing the patient to go about on crutches. If the disease is early detected and treatment adopted at once, in many patients it will abort, and they will recover with movable joints.

Where the tuberculous diathesis is pronounced, constitutional treatment should not be neglected—cod liver oil and iodide of iron, nutritious food, and exercise in the open air.

Carcinoma.

Six months ago I removed the breast and axillary glands of this patient, who is forty years old. She comes back to-day with a little nodule on the axillary border of the pectoral muscle. There is no trace of disease elsewhere, the old cicatrix being entirely healthy. In excission of the mammary gland for carcinoma, the axillary glands should always be removed, even when no signs of involvement can be discovered by the touch. Until the axilla is opened it is impossible to form any just appreciation of its contents. Infection may exist in this region, and not be recognized by the eye or the finger. In exposing this little mass of induration, I find it lies in the fiber of the pectoral muscle and appears to be perfectly isolated. I believe in repeating operations on any recurrence of carcinoma, for while we may not succeed in conquering the enemy, we can greatly retard the progress of the disease. The exception to such a course will be in cases where the cachexia has become pronounced.

Chronic Cystitis.

This patient is sixty years old. He looks haggard and worn by suffering. He complains of frequent micturition, pain along the course of the urethra, the urine containing a large amount of muco-pus, all of which are signs belonging to inflammation of the bladder. I hope the examination may disclose some cause which will not only explain his trouble, but may at the same time be susceptible of removal. I shall examine for stricture; no urethral narrowing is found. I next search for stone, and find no evidence of calculus, therefore we may eliminate stricture and stone from the rôle of causation. Possibly there may be an enlarged prostate. His age would naturally suggest such a condition. A finger in the rectum fails to discover any hypertrophy of this body, and consequently we have a case of vesical catarrh. Rich as are the resources of surgery it has no remedy for the cure of vesical catarrh. Much may be done, however, to palliate, and with this object in view, I shall direct that the bladder be washed out every second or third day with a solution of boracic acid (eight grains to the ounce of warm water) using three or four ounces for flushing the organ; and as an internal diluent and food, the free use of milk. Benefit will be derived from the administration of capsules of balsam copaiba or of sandal wood, especially when the water after standing deposits a gelatinous mass which adheres to the bottom of the vessel. A large number of diluents are at our command in these bladder troubles, as the decoction of triticum repens, of the trailing arbutus, and of uva ursi. Creasote often proves useful in drop doses 3 or 4 times a day. A certain number of cases do well under drainage, by opening the bladder either through the perineum or above the pubes, and keeping the viscus empty with a rubber tube.

COLLEGE OF PHYSICIANS AND SURGEONS—VANDERBILT CLINIC.

SURGICAL CLINIC—PROF. BULL.

Sarcoma of the Skin of the Neck.

Case I.—The patient was a man 45 years old, who presented a superficial indolent ulceration on the right side of the neck just behind the ramus and angle of the jaw. The ulceration was situated on an indurated bluish-red base, and was of an area of about one by two inches. It had existed for five years, beginning as a small yellow pimple, which was cut off in shaving and which afterward scaled over. The scales were picked off from time to time, but were soon replaced by others. The lesion gradually grew in size and became indurated. At no time did it heal, nor did it heal in one place and extend in another. Sometimes it would appear to be smaller than at others, but for

the past year there has seemed to be little variation in its size.

The patient had a chancre 22 years ago, followed by alopecia and an eruption on the body, but he gives no other syphilitic symptoms. Examination of the ulcer shows that it involves the skin, cellular tissue, and perhaps even the muscle; it is not painful, and its hard base is well pronounced.

These forms of chronic ulceration, said Prof. Bull, are usually dependent on some blood dyscrasia; they may be caused by syphilis, tuberculosis, lupus (which is now held to be a local tuberculosis), a carcinoma or epithelioma breaking down, or a sarcoma breaking down. The history of the present case does not aid much in diagnosis. It is not that of a gumma, which would come as a swelling, then soften and break down as an abscess; nor is it that of lupus, which usually commences in red spots, not elevated, gradually increasing and coalescing; and it is not that of epithelioma, which begins as an elevated or warty growth. Besides, in syphilitic ulcerations there is almost always noticed a disposition to heal in certain places and to extend in others, which is very characteristic. The throat, moreover, shows no evidence of cicatrices. Lupus is very rare in this location; and in carcinoma or epithelioma the ulceration would be more excavated and the edges more elevated. And if of such long duration the lymphatics would most certainly be involved; but they are not in this case.

The diagnosis therefore rests between syphilis and sarcoma, and is vastly in favor of sarcoma. The patient will, however, be put upon small doses of mercury and large doses of the iodide of potassium to give him the benefit of the doubt. Later a piece of the growth may be removed for microscopic examination; this should settle the question. Sarcoma of the skin is not a distinct pathological condition, but it has certain special clinical features. It is doubtful if simple removal of this growth will cure the disease. Its antagonism by erysipelas has been too often noted to be merely a coincidence. Erysipelas seems to produce a condition of the tissues which is unfavorable to the growth of the sarcoma, and thus it cures it.

Dr. Bull recalls a case of sarcoma of this form on which two operations were performed in one year; the wound would heal but, shortly after, the disease would break out afresh in the same spot. He operated for the third time and contemplated a fourth operation, but decided that the deep relations of the growth were too vital to admit of its complete removal by the knife without danger, and was satisfied with a thorough scraping out of the slough.

Shortly after the patient had two attacks of erysipelas, after which the ulceration began to heal, and the patient got well and has remained well since.

Chronic Rheumatic Arthritis.

Case II.—The patient was a man, thirty-five years old, a printer. He had a left elbow swelled, stiff and painful, which condition had lasted about one year. The motions of the joint were restricted by the pain. An examination showed the left arm somewhat atrophied above the joint; there was no pain on pressure; but severe pain on an effort to flex the arm. On rotating the fore-arm a crepitation was noticed. A hypodermic needle inserted into the joint showed entire absence of fluid.

The patient has a clap; can this be gonorrhœal rheumatism? No; because this form of rheumatism consists almost always of a chronic or subacute serous swelling of the joint, with no involvement of the bone, no atrophy of limbs, and is very seldom so acute as to be painful. The diagnosis is chronic rheumatic arthritis. There is here thickening of the synovial membrane and cartilage, and finally of bone, and the inflammation is a dry one. We would expect to find involved, also, some of the other joints, and notably the fingers. We do find one finger that has recently become stiff and without any apparent cause.

Tubercular Osteitis.

Case III.—The patient was a man, ten years old, who also had a left elbow joint enlarged, hot, painful, and with motion much restricted by pain. Six years ago the joint became inflamed and one year ago some operation was performed upon it, the scar of which is to be seen. The left arm is much atrophied. The amount of inflammation in the part, at present, is considerable.

This, said Dr. Bull, is evidently a case of tubercular osteitis; but we can go further and find the part of the joint involved. We discover, by careful palpation, the greatest tenderness to be over the head of the radius, and this corresponds with the incision of the former operation.

The patient is probably suffering from a recurrence of the tubercular disease in the head of the radius.

It is of importance, in reference to treatment, to know whether or not the joint has been previously excised; this can be readily determined by measurement and comparison with the sound limb.

Foreign Correspondence.

LETTER FROM THE SAMOAN ISLANDS.

(FROM OUR SPECIAL CORRESPONDENT.)

LEONE, TUTUILA ISLAND, Feb. 1, 1889.

The Samoan islands are especially interesting just now by reason of the war among the natives that is drawing Germany and America somewhat into the controversy. This is not the place to write of the political aspect of these interesting islands of the South Seas, but a few of the social and medical features may be of interest to the profession.

The Samoan Islands are known by geographers as the Navigator Group, and lie in latitude 12° to 15° south, and 172° longitude west. The climate is about the same as in all tropical islands, a dry and a wet season, just the reverse as regards the months, of course, of those found in lands north of the equator. It being now midsummer here we are in the midst of the rainy season. But rain does not bother the Samoan. He has no fine clothes to spoil. His dress is nature's own—except a small waist-cloth. This is true of women and children as well as of the men. The latter are fond of dressing the hair of the head in most fantastic styles—with oil, stiffened with lime and adorned with fancy wooden combs. During a rain his only concern is lest his hair become wet; and until he can seek shelter, he will hold over the head a large banana leaf, or wrap one carefully over and about the hair.

Of all the South Sea Islanders these people are the finest in form and feature; stalwart, strong, with even lips and bright eyes, and a complexion pleasantly browned, they present a fine appearance; and it is said that they are far more intelligent and bright than the Maori of New Zealand, the Papuas of New Guinea, or the Kanakas of Hawaii.

The island of Tutuila is one of the ports of call of the Oceanic Steamship Company of San Francisco, running to New Zealand and Australia. Sixty miles to the westward may be seen the mountain peaks of Upolo island, on which is situated Apia, and where the chief fighting is being done. Being rather warm in more ways than one there just now for an American, your correspondent contented himself with simply a view of the mountains of Upolo from the safe distance of Tutuila.

The Samoan islands are noted for being the home—natural habitat—of elephantiasis. It is endemic here. The inhabitants of Tutuila and the most eastward of the five islands constituting the group suffer most with it. Strange to say it is uncommon in other groups quite near, as, for instance, in the Tongalabu, Society, Friendly and Fiji Islands. I can find no satisfactory explanation for this fact. The natives say it is due to being in the sea water so much; but Samoans are not exposed this way more than the other islanders. Some of the cases now in Leone are sights indeed. One tumor weighs seventy-six pounds, another forty-eight pounds, besides the frightful enlargement of the legs and arms. A woman has a labial tumor of this kind weighing fifty-six pounds. Many of the cases are among aged people, who have been affected for very many years. The natives occasionally operate on each other, using either a razor or a prepared bamboo stick, which is said to cut equally well. As a rule, however, the operations are performed by naval surgeons who may be in port on some man-of-war. Conjunctivitis is also very common among persons of all ages and in both sexes.

There are no native doctors. The natives have learned to know the value of many of the native herbs. About one hundred and twenty-five remedies are in vogue and a few of these I learned. For rheumatism the oil expressed from a plant they call Feetan is used externally, and apparently is of much value. They practise massage, and this oil is rubbed in with a prolonged "*Lumi-Lumi*" (massage) which may have much to do with the cure. This *Lumi-Lumi* is not only a medical but a social practice. It is the method of treatment holding first rank in their eyes, and one is most luxuriously rubbed and kneaded for all complaints, from ennui up to the direst fevers; and a part of the hospitality of the wigwam is to offer a visitor a *Lumi-Lumi*. If one comes in from the bush tired and overheated, he is prevailed on to put a towel about the loins in lieu of the unnatural European dress, lie down on a cocoa mat and have a skillful girl expertly knead the body; to refuse is to be uncivil, a boor. There is no thought of there being any impropriety in this massage, and there is no immorality connected with it.

Another remedy is the expressed juice of the root of the Ivi tree. The tree bears edible nuts. This medicine has a reputation among the whites as well as the natives as being most prompt in curing dysentery—a disease not uncommon in the Islands.

The Pawpaw-tree flourishes in Tutuila and the fruit is used by the natives as food, and the milky juice of the unripe fruit as a digester of meats, etc. It is a veritable vegetable pepsin. If fresh meat is suspended in the tree, so that it can absorb the exhalations of the tree, the toughest meat will become tender. So powerful is the softening action of the juice that it must be used with caution, or the meat will drop to pieces. I find that some interesting experiments were made in 1879 upon this subject at the Royal Agricultural Museum, Berlin. A portion of the juice was dissolved in three times its weight of water, and this was placed with fifteen pounds of fresh lean beef in one piece in distilled water and boiled for five minutes. Below the boiling point the meat fell into several pieces and at the close of the experiment it had separated into coarse shreds. Hard boiled albumen, digested with a little juice at a temperature of 20 degs. C., could, after twenty-four hours, be easily broken up with a glass rod. The juice can be dried without losing its effect, but its efficacy in this respect does not appear to have been tested over a longer period than six months.

The Samoans have no regular meal hour. When anything comes in, or the cooking is ready, they eat. They will work all day in the bush on a young cocoanut as a diet. If there is plenty in the hut, they often will arise at midnight to eat most heartily. Like American Indians, they have a feast while food is about, even if it is a famine for days to come. Their appetite is something frightful. With the aid of some pawpaw one man will eat a sucking pig at a meal. Fish they like rare, and especially a small species—something like a sardine; only a hundred at a time will make a satisfactory meal. They sleep on cocoa mats, with a bundle of bamboo sticks as a pillow. These are hung from the beams of the hut during the day. During rough weather cocoa mat curtains can be let down around the sides of the hut, which in shape is like a large field tent, but made of a thatched roof, supported by bamboo sticks, with no flooring. No chairs are used, the position of etiquette being a squatting one, with the legs drawn underneath. If you stand while conversing with them in the "house," you must apologize, saying that you being a white man can not easily learn their graceful postures. Fashion is as strong an autocrat in the South Seas as in Paris.

At daybreak the entire village, men, women and children go to low water mark at the ocean beach, and defecate. In case of need one may go there at any time, but the great exodus from house to "habit" is the earliest hour of morning. A stone is used as water-closet paper. Women always urinate in a standing position; men squat. They are cleanly in their habits—wash the body after any work, first in sea water then in fresh. Soap is used when they can get it. Lime juice is a favorite application with the bath. A bark, similar to soap-bark used with us in America, is used by the natives for lathering their body, as well as for general washing purposes.

Puberty begins at eleven or twelve years of age. Parturition is short and attended with but little pain. The patient is attended by neighboring women. No prevention of conception is even thought of. Not even for cleanliness sake is a wash indulged in after connection. Children are loved, and a large family honored. Even what they are able to do on their own account in child bearing does not satisfy many families, and child adoption is common, and the child adopted becomes the special pet of the household. Criminal abortion and infanticide are almost unknown. Family and marital relations are strict; prostitution is unknown in Samoa. I have the testimony of officers who have spent many months among these people that the women, both married and unmarried, are most wonderfully virtuous. It is candidly admitted by even the enemies of mission work that this has been so only since the teaching of the missionaries has begun. Those thoroughly able to judge say that secret vice has been on the increase in direct proportion to the improvement in promiscuous connections. This vice is performed in the most disgusting manner, one sex practising it on the other with hand or mouth. Twin births are very rare. I should have mentioned that the woman after confinement is about in a few hours, and in a day or two at her usual occupations. Great care is taken to preserve the flow of milk; large amounts of cocoanut milk are drunk to favor a full supply.

A curious custom is for each sex to remove all hair from under the arms and around the pubes. The hairs are plucked and whatever still persists in growing is shaved off. The shaving utensil is a piece of broken bottle. It is looked upon as slovenly for men to wear whiskers, though much pride is felt in owning a handsome mustache. The bottle "razor" is also used for the face, and I understand that even the white

people often get shaved by the natives in a most dexterous manner with this odd shaving utensil.

Tattooing is begun in early youth, first about the thighs, then legs and arms, in both sexes, but is more thoroughly and extensively performed on boys. The operation is so painful that usually it is extended over a number of years. The boy is not a man, however, until all the regulation amount of fashionable tattooing is completed. Quite often the tattooing sets up an undue amount of inflammation, with the result of immense sloughing sores, that leave huge ugly scars. Hope is an important element in the issue of any disease the Samoan may have. During the war, men with only slight wounds would die if they were badly frightened, and, on the other hand, brave men would be shot through the body, come into camp to have the wound dressed, and be back to the battle within an hour, and finally recover.

The usual food of the natives is bread-fruit, bananas, cocoanuts, fish, fowl, and swine meat. They have a curious custom of burying a cooked biscuit made from bread-fruit, to use in case of famine, and for posterity to use in the same emergency. Some was recently unearthed near Leone, said to be fifty years old. Its smell was quite similar to that of Limburger cheese. Another remarkable custom is the religious rite of circumcision. This was found to be an established custom when they were first visited by white men.

And what do you think of the nude Samoan belle with the latest American craze of the chewing-gum habit? But in the case of the Samoan, it is her tooth-brush. The bread-fruit exudes a gummy material, which is used by the natives as a tooth-cleaner, by chewing the gum and working it about over the teeth.

It was laughable beyond measure to see the odd and delighted pranks the men and women made in looking in some small mirrors I presented to them. A partly worn-out jersey was given to a family—*pater familias* confiscated it, put it on, and then looked approvingly at himself in the looking-glass. Naked as father Adam, except a crushed-raspberry colored jersey! Can you imagine his appearance?

They are very fond of perfumes, and they have discovered a number of plants in the bush which yield scents. They use them chiefly in dressing the hair. They seem to be fond of the taste of kerosene oil, as they will drink a little of it; and their method of filling a lamp would seem to confirm this. To transfer oil into a lamp, either from a bottle or another lamp, it is first put in the mouth, and then squirted into the lamp which they desire to fill. Most of the oil comes from America. Our country is lighting up the rude huts of the savages in far-away South-land. In many other ways civilization is leaving traces of its contact with these people, and many of the most curious old customs are being modified or are passing away.

Their dead are buried in the garden adjoining the hut, close by the house, so that the lights in the house may shine out on the grave and cheer the spirit of the one lying there. The grave is marked all around with pieces of broken bottles, or stones.

The old are honored; grey hairs are respected, though baldness is looked upon as a disgrace.

I know no part of the world that possesses so many interesting features as Polynesia. Here is the spot for the tired doctor and for his patient. It will give me pleasure to answer any communication relative to this part of the world.

C. C. VANDERBECK, M.D.

PERISCOPE.

A Case of Reinfection with Syphilis.

The case is recorded in the *Giornale delle Mal Ven*, of a woman, 46 years old, who had contracted syphilis when a child from a schoolfellow. The patient suffered very severely at the time, and had the characteristic eruptions, tibial pains, sore throat, and subsequent abortions. Ten years later she had well-marked tertiary manifestations, which gained for her the soubriquet of *fistolosa*, in her village. While she was still in the same deplorable condition she was reinfected by her husband, who had a chancre on the penis and was covered with a roseolar eruption. She came to the hospital, and was found to have a typical indurated chancre on the labium with corresponding glandular enlargement, and a confluent rose-colored papular eruption all over the body. She also complained of general malaise and pain in the shoulders and knees. These symptoms promptly yielded to treatment, and there would not seem to be any reason to doubt the accuracy of the diagnosis in both instances. Indeed, that exceptions should exist in the protection afforded by a prior attack of syphilis is only what a study of other specific diseases would lead one to expect.—*Medical Press and Circular*, Feb. 6, 1889.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.00**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE DIAGNOSIS OF PREGNANCY BY EXTERNAL EXAMINATION.

In connection with the editorial in the REPORTER, November 24, 1888, on early signs of pregnancy, it is interesting to note that Dr. E. S. McKee, of Cincinnati, in a paper read before the Cincinnati Obstetrical Society, recently called attention to the value of external methods of examination for the diagnosis of pregnancy, in regard to which our country is behind the European practice. The art of diagnosticating pregnancy by external examination is best taught and practised in the immense hospitals of Dublin, of Germany and of France. In a recent work Credé teaches that a woman in labor and in the lying-in-state is diseased only through infection from fresh wounds. His maxim is: "He who does not examine a woman does not infect her." From the most careful digital examination some wound may occur, and therefore examinations should be limited to the fewest possible, or dispensed with altogether. Digital examinations are omitted for weeks together in the lying-in-hospital at Leipsic, especially if the health of the patient is not good. Credé teaches that the external examination should be given preference, and that internal examination should be employed only when demanded by the peculiar conditions of any case.

To follow this plan intelligently all the external means of diagnosis must be wisely and scientifically employed.

Inspection shows pigmentation of the face; the pigmented areola or the tubercles of Montgomery of the breasts; the size of the abdomen; and the brown line extending down the linea alba; the state of the umbilical cicatrix; a transverse furrow when the ring of Bandl has contracted; the striae on the abdomen; movements of the abdominal wall from activity of the fetus; and the height of the uterus.

Palpation proves the presence of the fœtus in utero and the number of fœtuses; the presentation, position, approximate size, and general conditions of the fœtus, and the relations of the uterus. Alternating pressure can produce *ballottement* by displacing the solid body, after carefully exploring and outlining of the uterus. If the abdominal walls are thick and the amniotic fluid abundant, and the points of diagnosis are difficult to determine, the examiner may seize the fundus of the uterus in the hand and force it down against the symphysis pubis, thus bringing the back of the fetus more in the range of palpation.

Abdominal *ballottement* may be made

with one or both hands. It is one of the most reliable signs of pregnancy. The sensation produced has been described as like the sensation produced by a lump of ice floating in a vessel of water and striking against the sides. When the placenta is placed anteriorly it can sometimes be detected by palpation. It is to be recognized as a fleshy mass which raises the palpating fingers from the fetal surface. The death of the fetus can often, though not always, be determined by palpation. The fetus can be measured by means of calipers. Applying them to the head and breech gives one half the length of the fetus, and consequently its age and the size of the uterus. The cord has even been detected passing over the back. Dr. McKee considers intermittent uterine contractions almost infallibly peculiar to the pregnant uterus. These contractions, which were first brought to notice by Braxton Hicks, are constant and not simulated by any other sign. Fetal movements may be sensible or visible. Extra-uterine fetation can only be detected when a distinct lateral tumor is palpable, which is quite distinct from the uterus, and auscultation must be practised before palpation, because manipulation disturbs both mother and child, increases the frequency of the heart beat and seriously modifies the auscultatory signs.

Percussion is the least valuable of the means of external diagnosis, and it is hardly possible to admit the claim that pregnancy can be made out in the second month by percussion. The amount of distension of the bladder is the most important thing that percussion can disclose at this period.

Auscultation is one of the most important of the methods of external diagnosis. In most cases the unaided ear is better than the stethoscope. Auscultation enables the examiner to hear the umbilical or funic murmur, the placental murmur, the pulsations of the abdominal aorta and the gurgling noises caused by the fluids and air in the intestines. A splashing noise due to the movements of the fetus in the liquor amnii may be heard occasionally, the fetal shock, muscular susurrus—the sound due to the friction of the uterus against the abdominal walls; and most important of all, the fetal heart sounds. The auscultator must not listen with the head lower than the body, for he thus causes an increase of the cerebral circulation and hears imperfectly.

It is a good thing for all medical men to know how much it is possible to learn in regard to the existence of pregnancy without making a vaginal examination; for occasions not infrequently arise when it is very desirable to avoid the latter, if it can possibly be avoided—sometimes for the sake of the patient, and sometimes for the sake of the physician. It is also good to know that a careful external examination may altogether obviate the necessity for more than a single vaginal examination when a woman falls in labor.

We say more than a single vaginal examination, because we think most obstetricians would like to make at least one such examination in order to ascertain the condition of the genital passages. But while we thus express our appreciation of the method advocated by Dr. McKee, we do not think it can ever take the place of vaginal examination in obstetrical practice, for the reason that many women would object to the investigation of their lower abdomens by sight, by palpation, by percussion and by auscultation with direct contact of the physician's ear. In most confinement cases a single and rapid examination with the finger *per vaginam* reveals to the experienced accoucheur all that he needs to know until the head reaches the perineum, and this is less formidable to the patient than the method described above.

None the less, it is well for medical men to be familiar with all the resources of their art, and external examination of pregnant and parturient women is a very valuable method, and, in certain cases, might be indispensable.

THE INFECTIOUSNESS OF PHTHISIS.

Ever since the discovery and isolation of the tubercle bacillus by Koch, those who accepted his theory that the bacillus has an etiological relation to the disease have spent more or less time in looking about for evidence that tuberculosis is an infectious disease, and contagious when circumstances favor the conveyance of the specific microorganism from a diseased to a healthy individual. This evidence has not proved easy to get—at least in such quantity as one might expect from the assumptions of the theory and the almost universal prevalence of phthisis. Still, medical records and unpublished experiences of intelligent observers indicate that cases of phthisis sometimes follow each other in a way which it is almost impossible to explain, except on the theory that the disease is both contagious and infectious.

In regard to the latter point, we may refer to the painstaking investigations of Dr. Lawrence Flick, of Philadelphia—to which we called attention in the REPORTER, Feb. 4, 1888—who discovered what seemed to him indubitable evidence that phthisis pulmonum is in a very marked degree an infectious disease.

An apparent confirmation of Dr. Flick's views may be found in a paper by Dr. F. Engelmann, of Kreuznach, in the *Berliner klinische Wochenschrift*, Jan. 7, 1889. In this paper, Engelmann describes with commendable directness and accuracy a series of cases of pulmonary tuberculosis developing in persons who in succession occupied the same apartment in a large lodging for glass-blowers. The facts in regard to the inhabitants of this apartment are the more significant in view of the comparative infrequency of phthisis in the occupants of adjoining and similarly conditioned rooms. As narrated by Engelmann, the developments of the apartment referred to point strongly to its infection with the cause of tuberculosis of the lung, and to the influence of this infection in communicating the disease to previously unaffected individuals.

There are certain vulnerable points in the temperate argument of Engelmann that the cases are to be explained only in this way; but no matter what conclusions may be arrived at by those who read it, it cannot be denied that taken together the facts stated make his conclusion a reasonable one. We can heartily commend his paper to the attention of men interested in investigating the contagious and infectious nature of phthisis, as a model of what contributions to the literature of the subject should be. His facts are stated with great clearness, and his inferences with thoroughly scientific moderation; and such evidence as he produces goes a great way toward establishing the opinion that the cause of tuberculous phthisis is particulate and may infect a given locality for a reasonable length of time.

THE TREATMENT OF ENLARGED PROSTATE.

With the careful study of disease of the genito-urinary apparatus which has been made in the last ten years, a number of methods of treatment which were formerly rare, or even unknown, have come into vogue, and the surgeon of to-day has a very different duty from that which devolved upon his near predecessors. This is peculiarly the case in regard to the treatment of hypertrophy of the prostate. Until within a few years palliative treatment was almost exclusively applied to this disorder; but of late years a great variety of operative methods have been proposed or discussed, such as perineal drainage, electrolysis, and the division or partial excision of the prostate through the perineum or from above the pubes. For these purposes the knife, electricity, and the galvano- or thermo-cautery have been recommended, and it is not easy to decide what method has the greatest claim to general adoption.

In an able paper read at the last meeting of the Association of American Genito-

Urinary Surgeons, and published in the *Annals of Surgery*, January, 1889, Dr. Francis S. Watson, of Boston, attempts to bring order out of the existing confusion and to lay down rules to guide surgeons in deciding what they should do in treating cases of enlarged prostate. After citing a number of opposing opinions, Dr. Watson studies his subject from, first, the anatomical standpoint; and, second, the clinical. From the anatomical standpoint he classifies prostatic enlargements according to the distance from the junction of the membranous and prostatic portions of the urethra to the furthest point of the median enlargement, the form of the enlargement, and the capacity and distensibility of the bladder. He finds that in twenty-eight out of thirty specimens which he has examined, a median enlargement constituted the chief obstruction to urination, and that—contrary to the opinion of Prof. Guyon—the great majority of cases are amenable to operative treatment. In twenty-one of the specimens the median enlargement was within reach from the perineum; in ten cases a supra-pubic operation would have been impossible; and in seven a perineal operation would have been impossible. In other words, neither of these methods is applicable to all cases, and either must be adopted or rejected according to the peculiar condition of any case. So far as immediate danger to life is concerned Dr. Watson believes that radical operations are not worse than palliative operations—puncture and drainage, but that perineal puncture and drainage are much safer than supra-pubic puncture with retained catheter. He thinks that many more cases die from unskilful catheterization than from radical operations performed by competent surgeons. For this, and because radical operations *are* radical he prefers them to palliative operations or catheterization. Of radical operations, he thinks the perineal preferable to the supra-pubic, because it is applicable to about two-thirds of all cases, and because it is safer.

His conclusion is one in which we entirely concur, namely, that the best plan in cases of hypertrophied prostate requiring operation, is to open the membranous urethra and explore the obstruction, and then to incise or excise as may be required or possible; and if the obstruction cannot be relieved by this route, to perform a supra-pubic cystotomy and complete the operation, following it with drainage through the perineum.

THE MEDICAL EXAMINERS' BILL IN PENNSYLVANIA.

With this number of the REPORTER we send to each subscriber a *Supplement* containing the names and addresses of the members of the Senate and House of Representatives of the State of Pennsylvania, and we urge all those who favor the passage of the bill to see or write immediately to the members of the Legislature with whom they have influence or acquaintance, or in whose district they reside, as the fate of the bill may be decided next week. We beg our subscribers to bear in mind that nothing is so likely to lead to the defeat of the bill as evidence of lukewarmness in regard to it on the part of the medical profession, and nothing is so likely to secure its passage as marks of interest in it by those who are supposed to know most about its merits.

As our readers well know, we regard this bill as one of great importance to the community, and hope that it will pass. We believe that it meets with the approval of the best members of the profession, who have no private or school interest to subserve. Its career is being watched with deep interest in remote parts of the United States, and other communities will gather encouragement for the work of reforming the methods of studying and practising medicine if it passes, and will be disappointed—and perhaps discouraged—if it fails to pass.

So let its friends lose no time in doing what they can to secure its passage; for those who oppose it will not be idle or slow.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

HANDBOOK OF MATERIA MEDICA, PHARMACY AND THERAPEUTICS, COMPILED FOR THE USE OF STUDENTS PREPARING FOR EXAMINATION. By Cuthbert Bowen, M.D , B.A. Small 8vo, pp. vi, 366. Philadelphia and London: F. A. Davis, 1888. Price, $1.40.

This is another of the books which reviewers are apt to condemn on principle; but, like some to which we have referred of late, it is so excellent of its kind that we cannot but give it its meed of praise. Critics, or no critics—it is clear, from the steady production of such aids to the memory, that there is a demand for them; and, as the demand is often met by men who know what students need as well as what they want, it is a pure assumption to decry them as usurping the field of better sources of knowledge. Many books of this sort are capital manuals. The one before us is such. It is not perfect, but it contains a great deal of useful information, which could be appropriated with great advantage by many practitioners as well as students of medicine. In going through it, we have been favorably impressed by the plain and practical suggestions in regard to prescription writing, and the metric system, and the other things which must be known in order to write good and accurate prescriptions. The discussion of individual drugs and preparations follows the usual classification according to their effects.

SKIN DISEASES OF INFANCY AND EARLY CHILDHOOD. By C. M. Campbell, M.D., C.M., Edin. Small 8vo, pp. 202. London: Baillière, Tindall and Cox, 1889.

This small volume discusses briefly, but with clearness, the various skin diseases incident to the earlier years of life. Additional value is given the book by including the exanthematous fevers. The salient features of each disease are presented, although in a work of this compass much that is valuable must of necessity be omitted, or very briefly passed over. In some respects the author's experience is not in accord with American observation. Thus, for instance, in recommending (p. 61) the oleate of mercury for inunction in the treatment of syphilis, with the statement that "the oleates certainly are more readily absorbed than any other preparation applied by inunction." The discussion on the oleates at a recent meeting of the American Dermatological Association, embodying this point, was practically unanimous in the negative. Dr Campbell modifies this statement, however, by adding, "but the ordinary mercurial ointment has always been satisfactory in my hands." Moreover we do not see, in this country at least, cases of *pemphigus contagiosus*, other that can be more properly classed under the head of impetigo contagiosa. The author accords a separate description to each, and evidently considers them as distinct. This being the case, the following (p. 38), if true, is to us more than significant: "It is a very curious fact that the next disease (impetigo contagiosa) which we have to consider . . . appears to be caused by the very same micrococcus as pemphigus (contagiosus)."

Although presenting, from a strictly dermatological standpoint, some misleading, if not erroneous views, such as the above, this small manual contains much that the general physician will find of service.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

223. Description of a Case of Coloboma of the Iris, Lens and Choroid: with a Study of the Visual Fields. By Charles A. Oliver, M.D., Philadelphia. From the *Transactions of the Amer. Ophthalmological Society*, 1887. 6 pages.

224. Nystagmus in Connection with Diseases of the Ear. By Charles J. Kipp, M.D., Newark, N. J. From the *Transactions of the Amer. Otological Society*, 1888. 18 pages.

225. The President's Annual Address. By Robert Battey, M.D., Rome, Georgia. From the *Gynecological Transactions*, 1888. 15 pages.

223. This is a most interesting pamphlet, illustrated with a beautiful phototype of the appearances of the eye, describing the condition of a woman whose peculiarities seem to have escaped attention until she was admitted to St. Mary's Hospital for typhoid fever, and came under Dr. Oliver's notice.

224. Dr. Kipp describes those cases occurring in his own practice—and incidentally refers to a number of others—in which increased tension in the middle ear produced marked nystagmus. In one case there was an exacerbation of a chronic purulent otitis media, and the nystagmus came on while the patient was walking in the street; in a second case there was a purulent mastoiditis and nystagmus came on while an abscess cavity communicating with it—and probably originating from it—was being syringed out; in the third case, nystagmus was produced by pressure on the mastoid process in a case of acute purulent otitis media.

The production of nystagmus under these circumstances is an extremely interesting occurrence, deserving the attention of pathologists, physiologists, and practising physicians; to all of whom we can heartily recommend Dr. Kipp's pamphlet as a very valuable contribution to the literature of this subject.

225. The first half of Dr. Battey's address is interesting, as it describes the present condition of the admirable society which is one of the most distinguished exponents of the art of gynecology in the world. The second part of his address is much less interesting because it brings to the front a private grievance, and introduces a suggestion which is utterly impracticable. From the first part, we infer that the American Gynecological Society is ready for some new members, if they are made of good stuff. This may interest a number of the readers of the Reporter.

Literary Notes.

—G. Masson, of Paris, announces the publication of a work entitled *Traité des Maladies du Testicule et de ses Annexes*, by MM. Charles Monod and O. Terrillon, two very well-known surgeons of Paris. The work will be issued in one octavo volume; price sixteen francs.

—Dr. Budin has been elected a member of the Academy of Medicine in the Section of Obstetrics.

CORRESPONDENCE.

Formula of Basham's Mixture.

To the Editor.

Sir: Please give me through the Reporter the formula for Basham's mixture. I am not able to find it.

Yours truly,
W. C. Eustis, M.D.

Farmington, Minn.

[The formula for Basham's mixture is given as follows in the last edition of the U. S. Dispensatory:

Tinct. of chloride of iron . . .	♏ lxxxiii
Dilute acetic acid	ʒ ii
Sol. acetate of ammonium . . .	ʒ xiv
Elixir of orange	ʒ vi
Syrup	ʒ i
Water	ad ʒ viii

Add the dilute acetic acid to the liquor ammon. acetatis, and then the iron, elixir, syrup and water.—Editor of the Reporter.]

Mistura Acaciæ.

To the Editor.

Sir: As several readers of the Reporter have written to me asking for the formula for *mistura acaciæ*, it will probably be well for me to say that this preparation of gum Arabic is not known to the United States Dispensatory, but is officinal in both the Edinburgh and Dublin Pharmacopœias. The Edinburgh process for making it is as follows:

Take of mucilage . . .	three fluid ounces.
Sweet almonds	ten drachms.
Pure sugar	five drachms.
Water	two pints.

Steep the almonds in hot water and peel them; beat them to a smooth pulp in an earthen ware or marble mortar, first with the sugar, and then with the mucilage; add the water gradually, stirring constantly; strain through linen or muslin. The Dublin process is similar. This mixture is known by the English names, "Gum Arabic Mixture," and "Gum Arabic Emulsion." As a menstruum for medicines for children, it is more agreeable than the Mucilage Acaciæ of the United States Dispensatory.

Yours truly,
J. B. Johnson, M.D.

Washington, D. C.,
Feb. 15, 1889.

Case of Meningocele—Correction.

In the article of Dr. Baum on a Case of Meningocele, published in the Reporter, March 2, p. 265, the word "gramme" in the second column, twelfth line from the bottom, should read "grain."

Allopathy.

To the Editor.

Sir: Why the general practitioner should have submitted so long to the epithet "Allopathic," must seem strange to the right thinking mind. There is no such body of physicians, so far as I am aware of, nor ever has been. It is a name that has been forced upon us by Hahnemann and his followers, and should have been discarded long ago, as it puts the general practitioner in a false light before the public. He is not the exponent of a particular theory or dogma, and therefore the term "Allopath" is entirely inappropriate. Let it be known to the public that we are the exponents of Scientific Medicine, and not dogmatists, and the intelligent and educated laity will see more plainly where we stand as a scientific body. Let every practitioner be scrupulously clear of using the term as applied to himself, and at the same time try and educate the general public that they may have a right and just understanding in reference to our position as compared with the different 'pathies and 'isms.

There seems to have heretofore been an indifference on the part of general practitioners to the effort to settling upon *us* that which places us in a false light before the world. The Homœopath, in referring to the regular physician designates him as an Allopath, in contradistinction to himself. Let us disabuse the general public of this understanding, and educate it to see our position as medical men: that we are a body holding to no particular system, theory or dogma; that we are a scientific body, endeavoring to advance our knowledge in the healing art, collecting wisdom from whatever source it may be found.

If the intelligent public could be made to understand our position as compared with that of the dogmatists, the 'pathies and 'isms would soon become extinct.

Yours truly,
W. L. Martin, M.D.

Rancocas, N. J.,
3d mo., 4th, 1889.

—It is officially announced that the Trustees of the University of Pennsylvania have appointed Dr. De Forest Willard Clinical Professor of Orthopædic Surgery, and Dr. George A. Piersol Professor of Histology and Embryology. These appointments were indicated in the Reporter, Feb. 9. Dr. Samuel G. Dixon has also been elected Professor of Hygiene.

Notes and Comments.

Treatment of Sweating Feet and Hands.

Dr. Unna (*Mon. f. prakt. Derm.*) recommends the treatment of cold, sweating feet with hot foot baths, which should be taken at night with some stimulating substance, such as spirit of camphor, mustard, or vinegar, thereupon drying the hands and feet and rubbing with a stimulating ointment, for example: ichthyol and turpentine, of each five parts; zinc ointment, ten parts. In the morning, after washing, the feet should be rubbed with cold water and exercise taken, the cold rubbing being continued until a condition of hyperæmia and warmth is produced. The stockings are to be powdered with starch powder, mixed with a little mustard. In the treatment of warm, sweating hands and feet, he recommends ichthyol, but without the warm water at night and the cold water in the morning. In the evening he recommends lukewarm water and rubbing with a simple ichthyol ointment (ichthyol, water, of each 5 parts; lanolin, 20 parts). In the morning the feet are to be washed with lukewarm water and ichthyol soap, and the lather rubbed off with a dry towel so that some remains on the hands and feet.—*N. Y. Med. Abstract*, Jan., 1889.

Inebriate Asylums.

Dr. T. D. Crothers, of Hartford, Conn., in an address on "Inebriate Asylums and their Work," delivered at Toronto, Can., draws the following conclusions as being supported by the latest teachings of science and experience: 1. Inebriate hospitals must take the place of jails and station-houses. Such places are dangerous in their mental and physical surroundings, by intensifying the degeneration, and removing the patient beyond hope of recovery. They are in many cases literal training-stations for mustering in armies of chronic maniacs that never desert or leave the ranks until crushed out forever. 2 Inebriate hospitals should receive the incurable inebriates, and make them self-supporting, and build them up physically and mentally. They would relieve the tax-payer, and relieve society of untold burdens of sorrow and misery. 3. Inebriate hospitals should receive the recent cases, and place them in the highest conditions of enforced health and vigor, and thus return a large number to health and sobriety again. 4. Inebriate hospitals can and should be self-supporting when once established. They should be managed on scientific business principles, like military training-schools. 5. Inebriate hospitals should be built from the money raised by taxes on the sale of spirits, on the principle that every business should be obliged to provide for the accidents which grow out of it. 6. These are the realities which every inebriate hospital is approaching, and which all experience points out as practical and literal in the near future. 7. The inebriate hospitals of to-day are only in the infancy of their work, contending with great opposition and prejudice, misunderstood, condemned, and working against innumerable obstacles. 8. The work of the present inebriate hospitals, notwithstanding all the difficulties and imperfections, has the grandest promise for the future, and encouragement for further effort in this field, along the line of scientific research. 9. Lastly, there is an intense personality in inebriate hospitals to each one of us. They may bring salvation and restoration to some one near and dear. They may be fountains of healing whose influence shall cross and influence our pathway in many ways. 10. Inebriate hospitals and their work are the great new land which only a few settlers have reached. They are calling to us to come up and occupy, and thus help the race on in the great march from the lower to the higher.—*Science*, Jan. 4, 1889.

Albuminuria and Yellow Fever.

Dr. Emilio Martinez, writing in the *Revista de Ciencias Medicas*, of Havana, on albuminuria in yellow fever, gives it as the result of his experience that the usual recommendation to judge of the gravity of the disease by the amount of albuminuria is untrustworthy, as he has met with cases, of one of which he gives details, in which the amount of albuminuria was very considerable, even though the disease ran an exceptionally mild course. In the case in question it appeared as if the poison confined its virulence almost entirely to the kidneys, the liver and other organs being but very slightly affected. A much more important point than the amount of albumin is, in Dr. Martinez's opinion, the amount of urea excreted per diem. This forms a guide to the activity of the oxygenating processes which are going on in the body. If these latter are retarded by the disease the amount of urea is very sensibly diminished. Its quantity thus stands in an inverse ratio to the gravity of the disease, and in this way forms a fairly reliable guide in prognosis.—*Lancet*, Feb. 2, 1889.

Treatment of Ingrowing Toe-Nail.

Dr. Theodore Clemens of Frankfort strongly recommends the employment of tinfoil in the treatment of ingrowing toe-nail. He first has the toe thoroughly washed with soap and carefully dried. He then envelops the whole nail with tinfoil, putting a strip between the portion that grows in and the raw surface caused by it. The tinfoil is fixed by means of a very thin layer of common wax, and the patient told not to wash the part, but to use dry bran for rubbing off the dirt. Of course the toe has to be repeatedly dressed with tinfoil; but, if the operation is carefully performed, it is surprising how long the tinfoil will remain intact, even when the patient is, as was usually the case in Dr. Clemens' hospital practice, very poor and very badly shod. The results are stated to have been most satisfactory, and are ascribed by Dr. Clemens not merely to the mechanical action of the tinfoil, but to the effect of the permanent contact of a combination of metals comprising iron, copper, arsenic, molybdenum, wolfram, and bismuth, with a moist and growing portion of flesh. This, he says, brings about in a few weeks the complete healing of the sore, and causes the nail to grow more slowly and in a more healthy manner.—*Lancet*, Feb. 16, 1889.

Case of Poisoning with Citrate of Caffeine.

T. Geraty reports a case of poisoning with caffeine in the *Lancet*, Feb. 2, 1889. At 9 A. M. before breakfast, a lady suffering from migraine took a dessertspoonful (equal to 200 grains) of pure citrate of caffeine, in mistake for the granular effervescing form of the drug. Mr. Geraty saw the patient immediately after the accident; the only complaint she then made was as to the nauseating taste. She was encouraged to eat a little porridge before having an emetic. As soon as the porridge was eaten, faintness and nausea came on; and a quarter of an hour after the reception of the poison there was semi-unconsciousness, grave depression, extreme pallor, complete relaxation of all the muscles and a decided inclination to sleep; pulse slow, soft, and very compressible; respiration slow and sighing. The treatment adopted was an early emetic (one-twelfth of a grain of apomorphia), which acted at once and very completely; the administration of small quantities of brandy; keeping the patient in the recumbent position, and the application of warmth. There was a well-marked rigor about an hour after the caffeine was taken. Consciousness was recovered about an hour and a half after emesis, and the faintness passed gradually away.

A Druggist Censured.

The Coroner of New York City concluded an inquest on March 5, in the case of Mrs. Storch, the victim of an overdose of morphine, purchased of a druggist. A thirteen-year-old sister of the victim testified that she was in the habit of getting morphine for the latter to the amount of 60 grains three times a week at the establishment of the druggist in question, and had never shown any prescription there, but said she had always taken the half-ounce bottle in which the drug had been originally procured by Mrs. Storch. The jury, in their verdict, censured the druggist for his carelessness and recommended that the statutes be strictly enforced and additional safeguards be provided.

American Physiological Association.

A regular meeting of the American Physiological Association was held in the rooms of Jefferson Medical College, Philadelphia, on Dec. 29, and at the University of Pennsylvania on Dec. 31. A number of interesting communications were read. Professor Reichert recounted experiments showing that the anterior columns of the spinal cord possess no irritability of their own, or that the power of excitability is confined to the posterior sensory columns He also showed that the rate of transmission of a nervous impulse differs under different conditions. Dr. J. W. Warren described some recent experiments showing that a sensory impulse, such as the explosion of a torpedo, reenforces the knee jerk, and drew the curve showing the variation of this reenforcement with the interval between the sensation and the knee-jerk. Dr. Donaldson showed specimens from which it could be seen that the effect of a long electrical stimulation is to decrease the size of the nuclei of ganglion-cells, and that the amount of this shrinkage is roughly proportional to the duration of the stimulation. Professor Martin in one paper gave the determinations of the minimal and maximal temperatures consistent with life that the blood supplied to an isolated heart could undergo, and in another showed that the variation in the amount of carbonic acid given off by a normal frog and one kept in the dark is due to the optical and not the psychic differences of the

two states; because a frog deprived of its cerebral hemispheres acts in this respect just like a normal frog. All of these papers led to interesting discussions; and the discussion of Dr. Reichert's paper induced Dr. S. Weir Mitchell to place at the disposal of the society two hundred dollars, to be devoted toward aiding research upon the rate of nervous transmission, especially in man. The society was hospitably entertained, and found much pleasure in visiting the laboratories of the Jefferson College and the University of Pennsylvania. The members of the society were invited to participate in the International Congress of Physiologists to be held in Basle in 1889.—*Science*, Jan. 4, 1889.

Medical Examiners Bill and the Medico-Chirurgical College.

At a meeting of the Faculty of the Medico-Chirurgical College of Philadelphia, held March 5, the following minute was passed:

"Believing that every reasonable advance of the standard of medical education is to the advantage of medical institutions and the profession, and feeling that the present State Registration Law imposes an onerous and unpleasant duty upon the medical colleges,

"Resolved that we, the Faculty of the Medico-Chirurgical College of Philadelphia, give our sincere and hearty support to the effort now being made to pass a bill for a State Board of Examiners, to whom shall be referred all applicants for license to practice medicine in this Commonwealth.

"Resolved that a Committee, consisting of Profs. Shoemaker, Pancoast, Waugh, and Keyser, be appointed to represent the College in influencing a favorable sentiment."

Appointment at Haverford College.

The Board of Managers of Haverford College, on March 1, 1889, appointed Dr. W. S. Hall Instructor of Physical Training at the college. He will be resident physician, general hygienic adviser of the students and sanitary adviser of the college, lecturer on physiology and hygiene, have charge of all the gymnasium exercises and of the physical questions that arise in connection with the games of the students.

Dr. Hall is a graduate of the Northwestern University and of the Chicago Medical College, in which latter institution he is now demonstrator of histology. He has been connected for two years with the Chicago Athenæum Gymnasium.

NEWS.

—The removal of Dr. Aby as quarantine officer of New Orleans has evoked vigorous protests from his medical and political friends.

—The Board of Managers of Swarthmore College have established a department for the direction of physical education, and have appointed Dr. J. K. Shell Director.

—Dr. John Guitéras, who has recently been elected Professor of Pathology and Morbid Anatomy in the University of Pennsylvania, sailed for Europe March 9, intending to spend the summer there in pathological studies.

—Prof. Kahler, of Prague, has been appointed to the Chair of Medicine at the University of Vienna, made vacant by the death of Prof. von Bamberger. Prof. Schrötter, the well-known laryngologist, has been charged with the establishment of a third clinic.

—The Pennsylvania College of Dental Surgery held its thirty-third annual commencement in the American Academy of Music, March 1, 1889. Dr. S. W. Gross presided and conferred the degree of Doctor of Dental Surgery on ninety-one graduates. Dr. Henry Leffmann made the valedictory address.

—Final experiments were made March 12 by the New York State authorities to satisfy themselves as to the best means of executing condemned criminals by electricity. Several dogs, four calves and a horse were experimented upon. In every case death was instantaneous and without sound or struggle. The experiments were under the charge of Dr. Carlos F. MacDonald, of the Auburn State Asylum, assisted by Mr. A. E. Kennelly, Mr. Edison's chief electrician, and Harold P. Brown, the electrical engineer.

—An epidemic of diphtheria is reported to exist at Gallitzin, Pa., since November, and about 100 deaths from this disease alone have occurred during that time in a total population of 2000. The disease is attributed to the disregard of the common rules of sanitation.

A malignant form of diphtheria has also become epidemic in Cranberry township, Venango county, Pa. Nine children have died within four days. In St. Petersburg the schools are closed and no public meetings are allowed.

—The Philadelphia *Ledger*, March 11, states that an autopsy was held March 10, on the body of a Mrs. Houckler, of East

Providence, Rhode Island, who died March 6, after nine days' illness, under the care of a "Dr." Etienne, who advertised himself as "a seventh son and a natural physician." He diagnosticated her trouble as "a combination of inflammation of the bowels, pneumonia and diphtheria." The autopsy showed that the patient had had none of the complaints named. This case may have an important bearing on the bill to regulate medical practice in Rhode Island, which was defeated in the Legislature during the previous week, but is to be reconsidered.

HUMOR.

"AND THAT IS SILVER ORE, is it?" said Mrs. Snaggs, as she examined a piece of curious looking mineral. "Yes, my dear," said her husband. "And how do they get the silver out?" "They smelt it." "Well, that's queer," after applying her nose to the ore. "I smelt it, too, but didn't get any silver."

A GOOD STARTER.—Old Mrs. Bentley—"When d'ye s'pose, Joshua, they're goin' to git these telegraph wires under ground?" Old Mr. Bentley—"I dun know; I see there's a prominent telegraph official died two or three days ago, an' is to be buried to-morrer." Old Mrs. Bentley—"Well, Joshua, that ain't much, but it's suthin'."

CONCENTRATED.—A Vassar graduate, out in the country, went into the stable of a farm-house. "Dear me; how close the poor cows are crowded together!" she remarked. "Yes, mum; but we have to do it." "Why so?" "To get condensed milk, mum." The sweet girl-graduate went off relieved and enlightened.—*Bristol Med.-Chir. Journal*, Dec., 1888.

PECULIAR ASSAULT AND BATTERY.—A queer case was recently adjudicated by the correctional tribune of Lübeck. An old family physician—a man past sixty-five years of age—was arraigned for assault and battery upon a patient. It appeared from the evidence that the latter was a girl in her teens, whom the doctor had ordered to take certain medicines. On making his next visit he found that she had failed to do so, and without more ado he turned down the bed-clothes and spanked her soundly, *propria manu!* The tribunal sentenced him to nine months' imprisonment and a fine. It is likely that the former portion of the sentence will be remitted, as his many patients have petitioned the court to this effect.—*National Druggist.*

OBITUARY.

RUFUS STANFIELD HARWELL, M.D.

Dr. R. S. Harwell was born in Robertson County, Tenn., February 22, 1820. He was graduated in medicine at the University of Pennsylvania in the spring of 1843. He began the practice of medicine in McNairy County, Tennessee, and remained there for three or four years. He then moved to Oxford, Mississippi, and practised there for five years. Thence he moved to Ouachita County, Arkansas, where he was an acceptable and successful practitioner to the day of his death, Oct. 6, 1888. He suffered for many years from asthma, which greatly crippled his usefulness. He was universally respected as a Christian, an honest man, and an excellent physician.

He leaves two sons and one daughter, living near Camden, Arkansas, and two half brothers, John V. and Marcus J. Wright, who reside in Washington, D. C.

ELWOOD HARVEY, M.D.

Dr. Elwood Harvey died at his home in Chester, Pa., March 3, of pneumonia, after a brief illness. He was born in Birmingham township, Delaware county, and was about 62 years old. He was graduated from Jefferson Medical College, and many years ago held a professorship in the Woman's Medical College of Pennsylvania. He was a prominent member of the Delaware County Medical Society and, with Dr. George Martin, of Concord, took the preliminary steps in May, 1850, for organizing the society in Chester.

During the war he was an assistant surgeon at the Soldiers' Hospital, Upland.

His wife and two sons survive him.

WILLIAM J. FLEMING, M.D.

Dr. William J. Fleming died in Philadelphia March 1, of Bright's disease of the kidneys. He was born March 19, 1828, and was graduated from the University of Pennsylvania in 1851. Shortly after this he went to Europe, where he visited the principal hospitals, returning after a two years' visit. He entered the army at the breaking out of the war as a surgeon and served throughout the war. At the close of the war he returned to Philadelphia and resumed and continued in practice up to the time of his last illness. He was a member of the College of Physicians and of the County Medical Society.

EFFERVESCENT SPECIALTIES

WM. R. WARNER & CO.'S

TRIPLE
(Effervescent)
BROMIDES

Advantages:—Useful in Headache, Nervousness, Sleeplessness, Migraine, Diurnal Epilepsy, Etc.

℞ Sodium Brom. grs. 15.
Potassium Brom. grs. 10.
Ammonium Brom. grs. 5.

Administer one teaspoonful in half a glass of water. Drink while effervescing. In Diurnal Epilepsy take a dessertspoonful three times daily until sense of taste is partly destroyed; after this reduce the frequency of dose, but keep the fauces in a benumbed condition.

WM. R. WARNER & CO.'S

CHALYBEATE
(Effervescent)
SALINE
(Ferric Saline Effervescens, Dr. Means)

℞ 1 gr. Citro-tartrate of Iron and 20 grs. of Soda.

Dose.—A heaping teaspoonful of the salt, containing 1 gr. Citro-tartrate of Iron and 20 grs of Soda, to be taken in a glass two-thirds full of water and drunk while effervescing. If a more decided effect is desired, warm instead of cold water may be used. In all cases this draught should be taken but once or twice a day, and then on an empty stomach, preferably before breakfast. No restrictions as to diet. One or two Pil. Digestiva (W. & Co.) may be taken at noon, before eating, as a dinner pill.

WM. R. WARNER & CO.'S
(ANTIPYRINE ET SODIUM SALICYLATE)

ANTALGIC
(Effervescent)
SALINE

℞ Antipyrine, 4 grs. Salicylate of Soda, 4 grs.
In each dessertspoonful.

Dose.—One dessertspoonful, to be repeated as often as the case may require Almost a specific in Neuralgic Headache. Prescribed in all cases where Antipyrine is used, with more better and more certain results.

WM. R. WARNER & CO.'S

APERIENT
(Effervescent)
SALINE

A pleasant and excellent aperient and refrigerant, very acceptable to the stomach. Given in all cases indicating the need of an active aperient, and to be given daily to all patients under treatment with Dosimetric therapeutics. (See Wm. R. Warner & Co.'s Dosimetric Granules.)

Dose.—One tablespoonful in half a glass of water.

PREPARATIONS SUPPLIED BY ALL LEADING DRUGGISTS.

☞ Samples of the above Salts furnished upon request.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO.,

PHILADELPHIA.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

CLINICAL LECTURE.

TRAUMATIC CROSSED SPINAL HEMIPARAPLEGIA; POISONING WITH BISULPHIDE OF CARBON.[1]

BY PROFESSOR J. M. CHARCOT,
PARIS, FRANCE.

Traumatic Crossed Spinal Hemiparaplegia.

Gentlemen: The patient who will serve for to-day's demonstration is a young man, twenty-four years of age, a slater by occupation. In appearance he is tall, thin, has a very agreeable face, and woman-like behavior. Notwithstanding this, he seems to have been very early in his life attracted by persons of the opposite sex; and it was in some affair with a woman that he became a victim of the accident the consequences and remains of which we shall study together to-day.

[1] Delivered at the Salpêtrière, Paris.

The accident, to which I have just now alluded, seems to have made a deep impression on his mind; so much so, that to keep the remembrance of this fact he had himself tattooed, at the upper and internal part of his left forearm, with the words "Death to unfaithful women." To the unfaithful women alone does he address himself; hence he seems to be still less pessimistic than the great poet, who generalized too much when he said, speaking of woman in general, that she was "false as water."

After this short digression, let us return to our subject. It was in March, 1880, when this man was only sixteen years old, that he had a quarrel with Italians, and at that time was struck from behind with a knife, which seems to have penetrated very deeply into the upper portion of the trunk, at the base of the neck; there still remains to-day, opposite the second and third dorsal vertebræ, a linear cicatrix about an inch in length.

You are probably all aware of the results of wounds of the spinal cord, especially those of the kind exemplified by our patient.

A man is leaning forward, when his adversary strikes him from behind in the line of the spinal column, and more often opposite the third and fourth dorsal vertebræ—as shown by the histories of the cases of Müller, Salmon, Joffroy—very rarely further down, as in the case of Viguès, in the dorso-lumbar region. The knife penetrates the intervertebral space, and, strange to say, the spinal cord is more often wounded by a hemi-lateral section on the side opposite to that at which the knife penetrated the skin. In this patient, the knife penetrated on the right of the spinal column, and according to the symptoms presented the lesion has reached the right lateral half of the spinal cord; you all know that such lesions are very dangerous, and usually end fatally in from eight to fifteen days after the traumatism. Our patient, as you see, seems to have been very fortunate, but I believe that in his case there has not been a complete left hemi-lateral section of the cord, but only a puncture; the knife probably penetrated only the middle of the left half of the cord by its point; and if at the beginning the symptoms pointed to an hemi-lateral section it is because a limited inflammatory process rapidly developed around the sectioned part—a true left transverse hemi-lateral myelitis—equivalent, as regards the production of a paraplegic form, to an absolute section. You will soon say to me, when I demonstrate to you the paraplegic phenomenon, that the spinal symptoms have immediately been carried to their maximum, with all their special characters, and hence one is entitled to think that a consecutive inflammatory process necessitates some time for its developing?

This is all true. My answer will be to refer to Brown-Séquard, who has shown that in hemi-lateral lesions of the spinal cord a simple puncture in one of the halves of the organ is equivalent, as regards the symptoms immediately observed, to a complete section; the logical difference being that the symptoms produced by the puncture are of a more transitory character; while those resulting from a section are permanent.

In our patient the first symptoms observed must be attributed to the puncture, while the later ones are to be attributed to an hemi-myelitis consecutive to the traumatism. As to the immediate effect of the injury, we have to rely on the testimony of the patient; he says he remained conscious for a long time, and did not immediately know that he had received a wound in the back; he remembers that he fell immediately, his left leg felt as if broken, as if it had disappeared. He was helped to get up, but his left leg could not hold him up, and he fell again.

From this account, the motor hemi-paraplegia was instantly produced, as a consequence, according to our hypothesis just stated, of a puncture of the cord. The patient was soon after his accident taken to the hospital, and then for the first time he became unconscious. He mentions the fact that he suffered at the time from retention of urine, which necessitated the use of the catheter for several days in succession. This is corroborative of our statement as to the existence of a myelitic process, which at one time had probably extended beyond the limits of the left lateral half of the cord; for this symptom does not belong to simple traumatic hemi-lateral section of the cord. An established fact is that when the patient awoke the left lower extremity was completely inert, paralyzed, while the right lower extremity had perfectly free movements, except that the sensation was entirely gone; this condition is Brown-Séquard's syndroma. The patient also remembers the diagnosis which was often repeated by the attending surgeon, namely, lateral hemi-section of the spinal cord.

Let me refer to what is called "Brown-Séquard Syndroma" by most physicians, while a very few call it Brown-Séquard's disease. I much prefer the term syndroma, because we have to deal not with a disease, properly speaking, but with a series of symptoms which can belong to different varieties of diseases. For instance, besides hemi-section, syndroma will present itself in myelitis, in intra- or extra-spinal tumors, syphilitic or otherwise; in tuberculous meningitis, affecting a lateral half of the cord, or producing a compression of the same.

In animals, our illustrious friend Brown-Séquard has shown that a complete hemi-lateral section of the spinal cord produces invariably a syndroma, the clinical characters of which have been well described by him under the title of spinal hemi-paraplegia with crossed hemianæsthesia. He has also later demonstrated that the same occurs in man, precisely in the same manner as it does in animals. Let us now examine the symptomatology of the affection under consideration, and let us suppose, as in our case, that the left half of the cord has been sectioned.

On the left side, which corresponds to the spinal lesion, we observe, first, a complete motor paraplegia of the lower extremity, a fact already described by Galien; second,

the skin of the left extremity is in a state of hyperæsthesia, and this hyperesthesia varies, going up toward the abdomen, according to the height of the spinal lesion, and is limited on this same side by a horizontal line—there is also a loss of muscular sensation; third, there is a certain increase in the temperature; fourth, more or less rapid muscular atrophy, with degenerative reactions; fifth, sometimes there are trophic articular changes, such as arthritis of the knee joint.

On the right side, the one opposite to the section, we observe first, cutaneous anæsthesia of the whole lower extremity, going up the trunk or abdomen, where it is limited by a more or less straight horizontal line; second, there is no increase of the temperature on that side; third, no traces of motor paralysis, of atrophy, or of increase in the reflexes; fourth, there are sometimes observed some cutaneous trophic troubles, such as an eschar in the gluteal region, a bed sore.

No vesical symptoms are manifest—this is the description of a recent case, of course; if the disease has been allowed to run its course for some time, we must anticipate a certain variability in the symptomatology, especially in those cases in which the patient has nearly entirely recovered the motor function in his paralyzed limb, such as will be encountered in those who have only suffered from a punctured wound, or from a temporary compression of one side of the cord; for it is clear, that only a temporary trouble would admit of the retrocession of these different symptoms, and a return to the normal state.

In our patient we still observe to-day the following state: On the left side, no trace of motor paralysis of the inferior extremity is to be found. This paralysis is said to have been a complete one for the first fifteen days following the accident; after which the motor power gradually returned; when he left the hospital, eight weeks after the accident, he felt a certain annoyance in that extremity, which lasted for nearly three years, but which now has entirely disappeared. As regards the temperature of this extremity, to-day it is even somewhat lower than the other; there is no cutaneous hyperæsthesia. The knee jerk is now quite exaggerated; there is no ankle clonus. The left extremity is very much atrophied, as is shown by the following figures: the middle of the left thigh gives a circumference of 39 centimeters (about 12 inches), while the same region of the right thigh gives us 43 centimeters (about 13 inches); the middle of the left leg gives us 26 centimeters (about 8 inches), while the right measures 33 centimeters (about 10 inches); no reaction of degeneration has been observed by Dr. Vigoroux, the medical electrician of the Salpêtrière, hence we must admit that this atrophy has been the consequence of the extension of the myelitic process to the anterior horns of the gray substance on the side of the lesion, yet has not produced complete destruction of these nerve cells.

On the right side there have never been observed any disturbances of motion. The reflexes are normal. There is no change in the muscular sensation, but there exists a great change in the sensibility of the skin. True anæsthesia is not really found in these cases, it is only an equivalent disturbance due to the existence of a spinal compression or of an organic lesion of the posterior columns. This I have called the phenomenon of dysæsthesia, which is noticed as follows: if you pinch your patient, he will feel it but will record the sensation after a striking delay, and even then without locating precisely the place where the excitation was applied. Moreover, the sensation becomes diffused above and below the excited point. Heat and cold when applied are also not recognized as such, but give rise to this diffuse sensation just mentioned. Let me remark here that this phenomenon of dysæsthesia, as far as we know, belongs only to organic spinal lesions and is not combined with the anæsthesia of hysterical patients. You see how easy it is, by the aid of an hypothesis, to interpret the existence of the remains of a spinal hemiparaplegia with crossed anæsthesia.

One point, however, must have struck you, and that is that the line which limits the diæsthesic anæsthesia does not extend as high as we might expect, the wound having been inflicted opposite the third and fourth dorsal vertebræ.

In the case of Müller, which is very similar to our case, the line went up as far as the level of the axilla; while in our patient it extends only to Poupart's ligament in front and to the lumbar region behind; this is certainly a singular anomaly; yet we must remember that Müller's case was a recent one, the patient having died in fifteen days, while our patient was injured eight years ago, which makes us admit that with time, there has been a progressive restoration of the injured parts of the spinal cord.

In our patient there is a very interesting example of spinal hemi-paraplegia with crossed anæsthesia, as a result of a traumatic lesion of the spinal cord. I would stop the examination of this case here, but I cannot overlook the fact that this patient was addressed to me by one of my ablest students in neuro-pathology, as an example of traumatic hysteria. The reasons put forward for this opinion by our colleague refer to the anomalies presented by this man, as regards, for instance, the spinal hemi-paraplegic syndroma; or again the limit of the anæsthesia on the right side, too low for an injury of the cord opposite the third or fourth dorsal vertebra.

In our lesson to-day, I have explained to you the reasons for these anomalies. Our colleague thinks that all the phenomena of spinal hemi-paraplegia have developed in this man as a result of suggestion, while he was in a peculiar mental state just after his accident, which could be compared to the somnambulistic period of hypnotics. He thinks that the lesson made before his bed on the syndroma of Brown-Séquard by the attending surgeon, was the origin of the suggestion. This we cannot admit. You all know that in cases of hystero-traumatic epilepsy, paralysis with or without anæsthesia following a local injury does not appear on the spot, does not present itself immediately; this fact is very important; in our case, however, the observation which was taken at the hospital at the time of his admission for the injury mentions the fact that the patient was already in a state of paralysis.

Although I reject absolutely the intervention of hysteria in the production of the syndroma of Brown-Séquard in our patient, I would not say that he is absolutely free from hysterical phenomena, for he has certainly shown traces of this affection; he even to-day, has applied to the hospital, not for his nervous trouble, but for coughing and spitting of blood. A careful physical examination showed him to be in a perfect condition, and we have admitted that these hemorrhages belong to the class of neuropathic hemorrhages so common amongst hysterical subjects. In respect to his neuropathy, we must not overlook his hereditary tendencies; his father is actually in an insane asylum, and his grandmother on the maternal side was subject to hysterical attacks.

Poisoning with Bisulphide of Carbon.

Most of you have probably heard of the manufacture of bisulphide of carbon; you know that the manufactures in which this preparation is used furnish us a certain number of patients who present symptoms of a nervous character.

Duchenne de Boulogne and Bouchardat a long time ago called attention to this intoxication; yet Delpech, in 1863, is the one who has correctly defined the train of symptoms which characterize the sulphide of carbon neurosis.

This poor man before us is a typical example of this intoxication; he is sixty-three years of age, has been a very vigorous man, but lately he has failed in strength. The symptoms which bring him before us have appeared for the past six weeks or two months. His family history shows no traces of nervous inheritance; he also seems to have been a sober man and is leading a regular life.

During his youth he lived in the country as a shepherd; he never learned to read, hence it is not intellectual work which has injured him. I have just said, a moment ago, that he was a sober man; we have a proof of that, for he has been working for a very long time in a factory where bisulphide of carbon is prepared, and in this business no drinking man is taken as a workman; and, in addition, we find no signs which would indicate that he drinks.

He has been in his present occupation since 1872, but he has not worked steadily, and occasionally he returned to his first occupation, that of digging. Still he had continuously worked in the factory for four months, when one day, while cleaning a bucket which was to contain the bisulphide of carbon, he presented the following symptoms: After having felt a sensation of suffocation, he had a feeling of heat in his scrotum, and fell without uttering a cry, as if he had had a cerebral apoplexy. His colleagues thought him asphyxiated, and they assert that during his unconsciousness, which lasted half an hour, no convulsions were observed. Finally he came to himself again and was able to walk home. The first two days after this accident, which he spent in his room, he does not remember anything of; on the third day, however, he felt a sensation of numbness, and on the following day, a well-marked paralysis had developed. That same day the right upper extremity was taken in the same way, but in a less severe degree.

Gentlemen, this hemiplegia which rapidly followed the apoplectiform attack was the first revelation of his nervous affection, the character of which we shall now define.

I shall ask our patient to stand up and to make a few steps before you, but do not forget that his hemiplegia dates back six weeks. Remark that while the patient walks, he drags after him his paralyzed lower extremity, as if it were an inert body. Note well that the paralyzed extremity always touches the ground, the patient does not attempt to lift it up at each step he makes You will find no trace of the movement of circumduction, which always exists in an old hemiplegia of organic origin; this fact will not be overlooked by those of you who are acquainted with it. If we now turn our attention toward the left upper extremity, we find that it is hanging powerless, very weak, and slightly deformed, probably because the fingers are extended straight, producing a right angle with the palm of the hand. We have here a spasmodic contraction, for we encounter an elastic resistance when we try to move the fingers in one way or the other, in flexion or in extension. We have here a spasmodic rigidity, but it is not the attitude of the hooked fingers which is observed in the hemiplegia of organic origin accompanied by contracture. By the dynamometer we obtain, for the paralyzed left hand, a pressure of 11 kilogrammes (29 pounds 4 ounces Troy), while the normal right one gives us 60 kilogrammes (160 pounds Troy). No increase of the reflexes is observed either in the upper or lower extremities, which already shows us that we have not to deal here with an ordinary hemiplegia of organic origin.

The next symptom observed is that cutaneous sensation is deeply affected, all along the paralyzed upper extremity, and also all along the corresponding lower extremity; you already know that this symptom is very rare in ordinary hemiplegia, we only find it when the lesion involves the posterior portion of the internal capsule, and even then sensation is never so much reduced as it is in this man. There is also a remarkable contrast between the cutaneous sensibility which is deeply involved and the motion, which, on the contrary, is not completely abolished; this again is not found in organic hemiplegia. Anæsthesia is not only present in the paralyzed extremities but is also found over the left half of the body, in front and posteriorly, and on the half of the head and face; and this anæsthesia involves not only the skin but also extends to the deeper portions, for the articulations can be twisted and pulled upon most energetically without the patient feeling it; he also is not aware if we displace his limbs, and cannot determine what position is given to them.

With these different facts just developed, those of you who are expert in the matter will not fail to recognize that we have to deal here with a case of hysterical hemiplegia. Is this man, who appears broken down, quiet, prostrated, showing signs of precocious senility—is he an hysterical patient? Yes, gentlemen, and those who are acquainted with the patients we see in this clinic, will not doubt it one moment.

Let us now establish the diagnosis of hysteria. I shall not return to the symptoms already mentioned: total deep and cutaneous sensitive hemi-anæsthesia, paralysis of the upper and lower extremities with loss of muscular sensation, absence of rigidity and absence of increase of the reflexes, while this hemiplegia is already more than a month old—these phenomena are already sufficient, but we have other additional symptoms.

In the first place, we remark that the inferior facial nerve is not involved; hence we have not a true hemiplegia, but an associated monoplegia. The convulsive movements of the right upper lip are not due to facial paralysis, but to facial hemispasm, which corroborates the diagnosis of hysteria. A remarkable fact is that you will find the facial hemi-spasm well indicated in several observations of poisoning with bisulphide of carbon, and especially in two observations of Mr. Delpech; but certainly the hysterical nature of these spasms has not been suspected. To the glosso-labial spasm we can add other strengthening symptoms; there is a well-pronounced contraction of the visual field on the right—the paralyzed side, while on the left the visual field is normal. Remark this fact of the contraction of the visual field on one side only, as it is rare. I have just said "permanent contraction," because such contractions are alone characteristic of hysteria in certain diseases. No dyschromatopsia, but a well-marked monocular diplopia is observed in this case; also an insensible pharynx; hearing power on the right side is very much reduced; taste is absent on the right side of the tongue. After all these classical symptoms of hysteria, it is not necessary to hunt further. Certainly our man has no convulsive attacks; we find no hysterical or hyperæsthetic spots; but these symptoms are not necessary to constitute the hysterical disease.

One word on the mental state of our patient. If I do not admit that there are

as many distinct kinds of hysteria as there are different origins giving rise to the affection, yet I admit that hysteria presents different forms, different varieties. A certain quantity of alcohol will produce a different drunkenness in different individuals; one will become very bright, full of fun; another, on the contrary, will remain very quiet, stupid. Our patient was very bright before his accident, and since then he has become quiet, morose, thinks himself worthless, and is quite discouraged. In hysterical men you will often find a condition of mental depression, and will also hear of their having most terrific dreams. This fact is also observed in our present patient; he is pursued nearly every night since his accident by lions, wolves—all sort of imaginary animals; his last dream, of which he spoke to us this morning, was that he found himself on the top of a mountain, and water was coming up gradually on all sides to drown him; he awoke in a state of great anxiety. If I insist upon these frequent psychical changes observed in hysteria in men, it is because some persons have been tempted to consider it as belonging to a traumatic neurosis, and having even a character separating it from true hysteria. This is not so. These same characters belong absolutely to the hysteria of man, and are found not only when the disease originates from a traumatism or nervous shock, but also when the affection is developed in consequence of the action of a toxic cause, saturnine or sulpho-carbon—or even under any cause. This particular mental state does not belong to a special form of hysteria, but is found in every variety of hysteria.

Having shown you that all the symptoms presented by our patient belong to hysteria, shall I say that hysteria is the disease observed by Delpech in so many patients, workmen in bisulphide of carbon factories? This would be going too far; yet we find in all his observations certain undeniable symptoms of this neurosis, such as the glosso-labial spasm, suffocation, *globus hystericus*, peculiar sensations in the genital organs, anæsthesias, hyperæsthesia, contractions, etc.

From our present knowledge we can safely say that most of the authors who have written on the sulpho-carbon intoxication have observed hysteria in some of its manifestations; hence hysteria would be the disease originating most frequently as a result of intoxication by the vapors of bisulphide of carbon. Hereafter then we must study more closely the relation existing between such a disease and hysteria. Amongst the observations recorded, there are manifestly certain symptoms which do not belong to hysteria; such are the acute and sudden pains which patients complain of as being located in their extremities, while at the same time the walking is uncertain. These patients have been looked upon as suffering from locomotor ataxia (sulpho-carbon ataxia); but I think we most likely have to deal with a peripheral neuritis, similar to the one observed in other intoxications, such as those in beri beri, or those arising from the use of alcohol; and that the motor troubles of the extremity resemble much more those resulting in the walk of the "stepper,"[1] than those of the tabetic patient. I am certain these troubles have no relation to hysteria.

Finally, we can say that there exist certain affections of the nervous system, which are due entirely to the action of vapors of bisulphide of carbon. Hereafter we must try to be more careful in our observations, so as to be able to differentiate correctly the symptoms belonging to hysteria from those which belong to the intoxication. Now that the patient has left the room, let me say one word in regard to the prognosis. This man will be cured with difficulty, this being the rule in hysteria of the male adult. This disease will last, notwithstanding our most careful treatment, several months, even several years. Suggestion after having produced the hypnotic state, cannot be employed on this patient, he not being capable of hypnotization; but suggestion in the awakened state (*état de veille*) can be employed with success against his paralysis. In addition to this treatment, the general tonics can be recommended; and finally, we must ask our patient to give up his occupation in a bisulphide of carbon factory.

—The commencement exercises of the Meharry Medical Department, and the Dental Department, of Central Tennessee College were held at Nashville, Feb. 22. The exercises marked the thirteenth anniversary of the Medical Department and the third of the Dental. This is the only Dental school for colored persons in the United States, and the Medical College is one of two in the country.

[1 Prof. Charcot probably means by the "walk of a stepper," a gait in which the feet are raised high off the ground (as in locomotor ataxia), but in which there is no exaggeration of their lateral or outward sway, and no irregularity in their rise and fall.—Editor of the REPORTER.]

COMMUNICATIONS.

HEADACHE IN INEBRIETY.

BY T. D. CROTHERS, M.D.,
HARTFORD, CONN.
SUPERINTENDENT OF WALNUT LODGE.

Recently I have seen several cases of inebriety, in which a history of early paroxysmal headache was prominent. The frequency of this symptom, in widely differing cases, has attracted my attention, and is evidently of much clinical importance in the prognosis of such cases The clinical histories of some cases will make this fact more apparent.

Case I.—John B., a steady drinker of twenty years' duration. His parents were both temperate, but his grandfather on his mother's side was a chronic inebriate. When about six years old he suffered from severe headaches lasting several hours, and reappearing every few weeks. They continued for many years, and resisted all treatment, becoming more and more severe in intensity and duration. At puberty they disappeared for two years, then returned. They seemed to follow from the exhaustion of overwork as a bank-clerk. From this time down to the age of twenty-four, he had constant recurrences of these attacks. Often they would be preceeded by great exhilaration and buoyancy of feeling, then suddenly merge into severe frontal headache, and later the entire top of the head would be sensitive, painful and very hot. This condition would last for eight or ten hours, then subside within a few hours and be followed by a profound slumber.

At twenty-four years of age, he began to use wine on the table, and within a year drank strong liquors. The headaches ceased altogether from this time and the use of spirits was kept up until he came under my care. Three weeks after admission he complained of great depression of both mind and body, lasting for several hours. These attacks of depression continued, only growing less in intensity, until he was discharged. His history since then has not been obtained.

Case II.—William H., a periodical inebriate, began to use spirits while in the army. His father drank to excess at long intervals up to his death. His sister was hysterical and died of consumption early in life. The patient began to suffer from severe headaches soon after puberty.

These attacks came on unexpectedly and without any apparent cause, and after several hours of agonizing pain, ended in sleep, from which he awoke free from headache and well. They were called "bilious" attacks, and were variously treated, but with no results. In the army the surgeon ordered large doses of spirits and quinine, and from this time the headaches disappeared. He became an inebriate, and twenty years after came under my care and recovered and was discharged a year later.

Case III.—B O., an irregular inebriate, who had been a lawyer, politician and active man of the world. He drank to excess at irregular times and places. His mother died of consumption soon after his birth. His father was a nervous, passionate man, who died of apoplexy. He had headaches from infancy; sometimes they were severe and he had to go to bed, at other times he could keep at his business.

At twenty years of age these headaches were so severe that he was confined to bed for a week after the attacks. They came on several times every year, and resisted all treatment. He had been an abstainer, for the reason that beer and spirits produced intense nausea. When about twenty-four he was given large quantities of brandy for this headache, and ever after he could use it. When the pain subsided he used spirits largely. As he became more addicted to spirits the headaches died away, and for twenty years before admission had not been noticed. A few weeks after coming under my care they returned, but were less severe and continued while he was under treatment. They seemed to be preceded by mental and muscular irritation for several hours, and were followed by great exhaustion.

These three cases are more prominent types of nerve paroxysms preceding inebriety. In many cases there are histories of irregular periods of headaches, occurring before inebriety appeared. In some cases headache appeared first at puberty and was very intense for a time, and then subsided. In others, severe headaches of childhood disappeared at puberty or broke out again in later life, and merged into inebriety. The presence of headache in early life is always a grave symptom of brain exhaustion and neurotic disturbance from heredity. In such cases there is a strong probability that some neurotic disease will appear in later life, from the slightest exciting causes. When these headaches come on later in life, some conditions of profound exhaustion and nerve disturbance are present. It may be stated

as a general fact that a history of severe headache in a case of inebriety is a hint of serious nerve and brain disorder, requiring constitutional treatment. When they appear after inebriety is established, in cases in which there is a possibility of syphilitic infection, specific treatment is required.

When they disappear from the use of spirits the prognosis is grave, especially in those cases in which they return when the alcohol is withdrawn.

In some cases these headaches resemble epileptic seizures, in the suddenness and intensity of the paroxysm, and the irritation and depression which follow. They may be most aptly called "nerve storms," or discharging lesions, of the higher centers. A practical point would be never to use spirits in these cases of paroxysmal headaches, for fear of fixing and developing the graver disorder of inebriety, or some allied insanity.

Moreover, when headache is found to be prominent in the history of inebriety, the case is more serious, and requires more careful study and treatment. In all probability the presence of headache preceding inebriety is only a hint of brain degeneration that may or may not merge into inebriety, depending on some special exciting causes. When headaches follow inebriety, the conditions and causes are complex and grave.

Medical art and skill can do much in both cases. In a case under my care in which the inebriety began with the use of spirits to relieve these paroxysms, Turkish baths broke up these attacks, and the inebriety disappeared as the health improved.

In another case of inebriety in which severe headaches followed the drink storms, rest, improved nutrition, and general tonics, baths, and constitutional remedies resulted in permanent recovery.

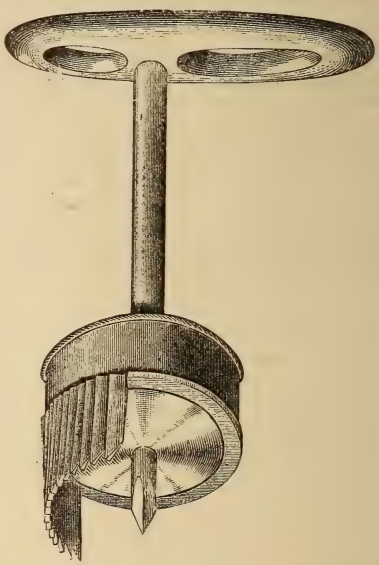
Paroxysmal headaches in childhood and following puberty should always attract attention, and receive careful medical treatment. Narcotics of all kinds are both dangerous and uncertain. The only safe remedies are tonics, nutrients, and all means to build up and strengthen the organism.

—*Science*, Feb. 15, says that Professor Ruata of Perugia is authority for the statement that there are annually in Italy nearly 300,000 cases of typhoid-fever, of which number 27,000 prove fatal. One-third of the persons in Italy who reach the age of forty-five have the fever, and in some districts more than three per cent. of the population die from this one cause.

THE SEGMENT TREPHINE AND AN ASEPTIC TREPHINE.[1]

BY JOHN B. ROBERTS, M.D.,
PROFESSOR OF ANATOMY AND SURGERY IN THE PHILADELPHIA POLYCLINIC.

The frequency with which operations are now done upon the skull and brain has made apparent the need for improvement in our instruments for opening the skull. Seven years ago I published[2] an account of my experiments with the surgical engine, as a means of making openings in the skull; and I still believe it an excellent and safe means of effecting access to the cranial contents. The chief disadvantages are the expense of the engine and its liability in ordinary hands to get out of order. This latter objection held good at least in one hospital with which I have been associated.



The ordinary trephine, either cylindrical or conical, will probably be used much more frequently, therefore, than the surgical engine; hence suggestions to improve its character are not inadmissible. The "segment trephine," described in the *Operative Surgery of the Human Brain*,[3] is, I think, a valuable instrument with which to deepen any portion of the groove surrounding the button of bone to be removed, without cutting along its entire circumference. The skull is often very much thicker in some parts of the area of operation than in others,

[1] Read at the meeting of the Philadelphia County Medical Society, February 27, 1889.

[2] *Philadelphia Medical Times*, 1881-82, xii, p. 206.

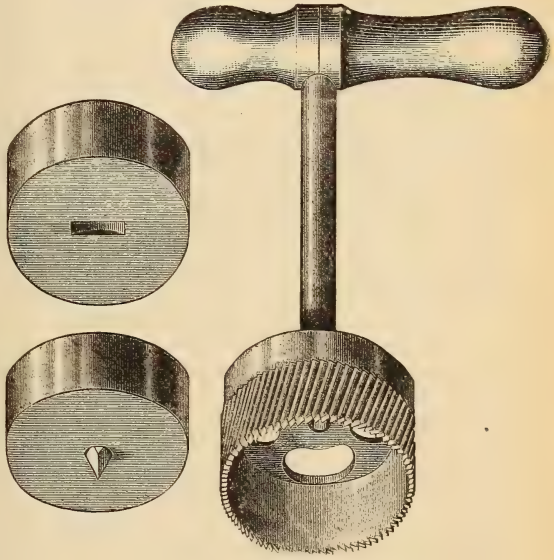
[3] Page 78.

and the ordinary trephine has to be tilted to avoid injuring the cerebral membranes at the points where the skull is thinnest. Tilting is not always easily done when the trephine is large and deeply imbedded in the bone. A "segment trephine," having the same radius of curvature as that with which the operation was begun, enables me to cut more deeply and with great care at any selected part of the groove. The accompanying illustration renders a detailed description of the instrument unnecessary. The cutting edge extends one-third of the circumference, and the centre-pin, not requiring retraction, may be immovably fixed to the head of the trephine. The instrument has no groove in the stem or handle to collect septic matter, and is readily cleaned.

A serious objection to the ordinary trephine is the fact that it is almost impossible to get assistants and nurses to keep the centre-pin, and the tubular stem in which it slides, perfectly aseptic. Indeed, it is difficult, with every intention of perfect cleanliness, to keep the hollow stem of the instrument absolutely clean. I have endeavored to remedy this objection by making the stem solid, and substituting for the ordinary sliding centre-pin a circular block of metal, accurately fitting into the crown of the trephine, with a point upon its lower extremity.

As soon as the surgeon has cut a groove deep enough for the teeth of the trephine to be maintained in position upon the skull, the central block is taken out of the crown of the trephine, and the operation continued as with the ordinary instrument, after retracting the centre-pin. Upon the upper surface of the block is cut a shallow slot, into which fits a slight projection from the upper part of the trephine crown. This compels the block to rotate with the rest of the trephine when the operator is making the first incision into the bone. The trephine itself is made as thin as possible, in order that the groove between the disc of bone removed and the rest of the skull may be very narrow. The button of bone, when replaced, can then be held in position more readily than if the groove is a wide one. I believe that after using a thin trephine, such as this, it at times will be well to stitch the button of bone into position by catgut sutures passed through the periosteum, which may be allowed to remain upon the surface of the disc of bone, and upon the skull adjacent to the trephine opening.

The crown of the trephine must not be too conical, because such a trephine in cutting through the thick skull makes the outer portion of the incision a very wide one. I am inclined to think that a surgeon of even moderate skill never needs a conical trephine to prevent his plunging the instrument into the brain; a cylindrical one should be just as safe in his hands as a conical one. An advantage in having the crown of the trephine slightly conical, when a large instrument is used, is that the instrument is less liable to become jammed in the groove. This annoyance not infrequently occurs on account of irregularities in thickness of the skull, especially when a large surface is included in the trephine. It is more apt to take place, I think, when the groove is made by a cylindrical instrument, which does not make the external aspect of the incision wider than the internal.



The weight of the metal handpiece can be minimized by fenestræ, or by making the handle hollow. It is best to attach the handpiece to the stem eccentrically, as suggested by Horsley, since the hypothenar portion of the palm needs a longer lever than the thenar.

This aseptic trephine, it will be seen, is somewhat similar to the safety trephine of Hopkins,[1] who suggested the use of a cylindrical block instead of a centre-pin, because of the possibility of the surgeon forgetting to withdraw the centre-pin, and, therefore, wounding the dura mater. His device contained a spring to keep the block thrust forward, and was therefore very difficult to clean. In fact, it was not constructed with an idea to facilitate asepsis, but to prevent careless puncture of the dura.

SOCIETY REPORTS.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, February 25, 1889.

The President, ALEXANDER S. HUNTER, M.D., in the chair.

By special order, the discussion opened at the last stated meeting by a paper by DR. SIMON BARUCH, on

The Value of Water in modern Therapeutics,

was continued by a paper sent by DR. A. JACOBI and read by the Secretary. In this paper Dr. Jacobi reviewed his writings, some dating back over twenty years, recommending and describing the use of water for stimulating the circulation, reducing the temperature, and for its influence on local inflammatory swellings. Among the diseases in which he had given it especial attention, were typhoid fever and diphtheria; he had also used it extensively in various other affections some dozens of years, and twenty years ago succeeded, he said, in getting himself expelled from an institution because he was found guilty of using cold water in the treatment of sick children.

DR. HENRY DESSAU had found water as necessary in the maintenance of the health of children as of adults. There is still a tendency to overfeed infants, and not to allow the stomach time for rest between meals. The use of water as a drink would often allay the thirst of the child and its demand for too frequent feeding. In diarrhœa it relieves dryness of the mouth, and supplies a want arising from loss of intestinal secretions. Some have said it increases the diarrhœa, but such has not been Dr. Dessau's experience. He has also found a plentiful use of cold water as a drink in the nephritis of scarlatina a benefit because of its gentle diuretic and cleansing effect on the kidneys. The bath, he said, is the best tonic we have, and should be used regularly every day in infants four or six months old. In strumous and rachitic children the cold bath daily employed is one of the best protectives against catarrh from sudden changes of temperature. Cold sponging of the chest and spinal column is the best remedy for laryngismus stridulus. He also employs the bath in convulsions in children, usually the cold bath if the convulsions are a part of a fever, and the hot bath when they are due to peripheral irritation, such as an overloaded stomach, dentition, etc. He also employs cold water in the treatment of chronic diarrhœa in infants.

DR. DESSAU said he had formerly published an article in the *New York Medical Journal* on the endermic use of water for allaying pain, and said that it seldom failed. It seems to be best adapted, however, to the relief of pain of nerurotic rather than of inflammatory origin.

DR. AUGUST SEIBERT demonstrated the ease with which the stomach of the infant can be washed out. He uses a soft rubber tube, of small size, allows the water to run in from a graduated measure, say half a pint, and empties the stomach by siphon action. The temperature of the water should be about 102° F. The three disorders in which this treatment is especially useful are, cases of deranged stomach from simple overfeeding; chronic gastro-intestinal or enteric catarrh, and cholera infantum. One washing is usually sufficient in the first class, several in the second combined with proper feeding, and as a rule patients of the third class are also thus cured, Dr. Seibert having saved twenty-six out of twenty-eight cases last summer. No medicines were employed.

DR. VINCENT ZOLNOWSKI read a communication, and first emphasized the importance of a careful inquiry into the patient's previous history, the present condition of his urine, thoracic and abdominal organs, and general health, before applying hydropathic therapeutics. The treatment, he said, varies according to the condition of the circulation, temperature, age, and vital resistance of the person. Water can be used as an antiphlogistic, sedative, excitant, tonic, derivative and solvent, but the two general methods to be observed are its use as an excitant on the one hand, and as a depressant on the other. As an excitant it must be used quickly, the degree of temperature proportioned to the irritability to be overcome—the less the irritation the lower the temperature employed. The depressant method is of two qualities, antiphlogistic and sedative. In the former the heat is withdrawn slowly; but moderate temperatures are used in these cases only until the excitement is allayed. The sedative method is recommended when the nerves are greatly excited. Water used internally as a drink and by enemas acts mechanically.

Dr. Zolnowski cited, among other interesting cases, one pronounced schleroderma by some of the most eminent physicians of New York City, who thought the progress would be rapid to a fatal issue. The use of

water, however, in the form of baths, half-baths, douches, packs, local application of wet cloths, etc., for two years or more, have now overcome the rigidity and pain which had existed in all the muscles of the body, until at present there is stiffness only in the fingers. He also cited a marked example of the morphine habit in a physician, overcome by hydropathy; likewise some neurotic affections due to the lithæmic habit.

Dr. Ralph Parsons gave his experience with water in the treatment of mental and nervous disorders, and said he has found the hot bath of special benefit in maniacal excitement, and uses the warm bath at bed time to overcome insomnia, following it by inunction of the skin. The cold bath should be used with care in the insane, and should not be employed by surprise, for while it has been claimed that some are restored to reason by the unexpected cold plunge, he believes much more harm has been done than would counterbalance the few cases of favorable issue.

Dr. Van Valzah gave the conclusions he has arrived at after seven years experience with hydropathic treatment, especially in gastro-intestinal disorders, such as gastritis and dyspepsia. The use of the water internally in these affections should always be guided by judgment. Cold water promotes upward peristalsis, while hot water produces downward peristalsis. Hot water before meals should be sipped, and taken an hour and a half before. Special caution should be taken when there is a tendency to hemorrhage or during menstruation. A moderate amount of hot water stimulates thirst more than the same amount of cold water in diabetes. The safest general rule to be guided by in the administration of water is the condition of the urine, which should be kept, if the use of water will do it, at from 1.016 to 1.018, and of not too high color.

Dr. Wallian spoke of the principles involved in the use of water in fever and other affections, and remarked that an intelligent treatment would not be adopted until physicians recognize fever as a symptom instead of as a disease. Instead of paying so much attention to the cure of disease by drugs, one should remember that the cause of all diseases is unhealthy surroundings, improper food and drink, or excessive or deficient function of parts of the economy; and the physician should restore the normal circumstances. A most important indication is to prevent accumulation of waste and poisonous products. The use of water will do more than anything else to stimulate the functions of the skin. He deprecates the tendency to rely upon antipyretic drugs in fevers. He thinks cold water will not replace hot water in the treatment of typhoid fever.

Dr. Holcombe gave an account of his own case, that of Bright's disease, supposed to have been far advanced, and of gastric disturbances, and his restoration to health, after unsuccessful trial of various other measures, by the use of flesh diet largely, and of water.

Dr. Hungerford, of Connecticut, said he had had a different experience with the treatment related by Dr. Holcombe, he himself having been a sufferer from gastritis, and was made much worse when he tried the meat diet and water.

Dr. Simon Baruch made some closing remarks, among others that he had found the warm bath of little use in the convulsions of children, for by the time it was ready the convulsion would be over or prove of a nature not to be remedied by the bath. In convulsions due to hyperpyrexia, however, nothing equals the graduated cold bath as a preventive measure.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 7, 1889.

The President, A. L. Loomis, M.D., in the Chair.

Dr. Francis Delafield read a paper on

The Treatment of Acute and Subacute Nephritis,

which, he said at its commencement, was not intended to bring forth any new drug or method, but to determine how plans of treatment and drugs already employed may be applied intelligently in individual cases. A review of works by German, French, and American authors show that there is a disposition at the present time to direct treatment to the symptoms of nephritis rather than to the nephritis itself, and he proposed to view the subject from the opposite standpoint.

It is necessary at the outset to separate acute from subacute nephritis. After a brief review of the pathological changes present in acute nephritis, a disease most frequently seen after scarlatina, diphtheria, and some other acute inflammatory affections, he based on these his views regarding appropriate treatment. In mild cases, he said, no treatment is necessary further than to keep the patient in bed and give fluid diet.

In the more severe cases other treatment will be required—and the first condition to be met is the nephritis itself—and besides that, arterial tension should be lessened. In treating the nephritis itself it is to be observed that although the quantity of urine is small, its quality is good; that the secretion of urine relieves the congestion, and therefore it is better that the kidneys should be active than at so-called rest. It should also be remembered that as long as the congestion continues the quantity of urine will be diminished, and a considerable diminution for several weeks is often well borne; and it is not necessary always to try to get the skin and intestines to do the work of the kidneys. It is wiser, by relieving congestion of the kidneys, to get them to do their work, for the moment this takes place the congestion will still further diminish. To relieve the congestion, cause the blood to collect at the surface of the body by the application of heat to the entire skin; use dry or wet cups over or heat over the lumbar region; use empirically calomel or sulphate of magnesia in small doses repeated at short intervals until the bowels begin to move; use also such drugs as will decrease the arterial tension. It is not expected to bring the urine up to the full quantity as long as congestion continues, but only to the point of securing safety. The febrile movement requires no treatment. Prostration, nausea, and vomiting call for rest in bed and fluid diet. Anemia can be successfully treated only after convalescence sets in.

Cerebral symptoms have received most attention. They accompany contraction of the arteries with increased tension and labored heart action. To overcome the arterial tension, aconite, chloral hydrate, and opium are suitable, and are preferably given in small doses, so that their use can be continued for some time. When arterial tension exists it should be reduced, without waiting for the development of cerebral symptoms.

In opposition to the condition present in acute nephritis, there is, in subacute nephritis, long continuance of the inflammation, but no congestion; the exudation is of the profuse, almost dropsical character met with in other subacute inflammations, as in pleurisy with effusion; and there are permanent changes of the stroma and glomeruli of the kidneys. The interference with the renal function consists in diminution of the solid constituents of the urine. The quantity of the fluid is often increased. The symptoms of the disease are largely due to the effect upon the blood and nutrition of the body. The anemia, dropsy, and loss of strength are prominent features. Contraction of the arteries is absent, or present only at intervals, and the cerebral symptoms are chronic rather than acute. The symptoms of acute nephritis may be present during exacerbations. Only very few patients seem to recover permanently. The conditions requiring treatment are: the subacute nephritis, the changes in nutrition and in the composition of the blood, the dropsy, the condition of the arteries, the cerebral symptoms, and the acute exacerbations of the inflammation.

For the nephritis the patient should reside in a warm climate and lead an out-of door life. If his home is in a cold climate he will have to stay in the house much of the time. Except during the exacerbations he should take as much solid food and fats as he can digest. The excessive use of milk and mineral waters is to be avoided. It is possible that opium and bichloride of mercury favorably affect the nephritis. The anemia is a most important symptom, and requires iron and oxygen, together with massage and relief of constipation. The dropsy may be only an inconvenience, or it may be a most distressing symptom. It often reaches its greatest development with low arterial tension and large excretion of urine. In some cases the treatment of the anemia and regulation of the diet answer also for the dropsy. It is not wise to increase the urine more than is sufficient to enable the patient to excrete his five hundred grains of urea a day. The fluid taken should not exceed the urine passed. In extreme cases of dropsy it is necessary to purge, sweat, puncture the skin, or tap serous cavities.

High arterial tension, should it exist at any time, may be controlled with nitroglycerine, chloral hydrate, or opium. To avoid cerebral symptoms one must watch the amount of urea excreted and the condition of the arteries. The acute exacerbations are to be met as in acute nephritis.

Dr. T. E. Satterthwaite sent a communication, expressing his views on treatment, which were modified in different cases according to the pathological condition existing in the kidney and the lesions elsewhere in the body, which the renal affection might accompany.

Dr. A. Jacobi disapproves of the use of caffeine for cerebral symptoms when high arterial tension exists. Bichloride of mercury, he said, is useful in cases of nephritis when one is unable to distinguish between

the subacute and chronic form; and it should be administered in small doses and continued for months. Subacute nephritis in men who have reached the age in which the arteries become changed is much benefitted by bromides, given in doses of not more than fifty grains a day, and combined with general treatment.

Dr. Kinnicutt laid stress upon the value of vaso-motor dilators in arterial tension, such as the nitrites, and said that on theoretical grounds at least he preferred not to give digitalis.

Dr. J. West Roosevelt pointed out the source of danger in arterial tension, and said it is direct only when the arteries are diseased, and acts indirectly by causing a strained heart to do still greater work, and by causing anemia of the tissues through contraction of the arterioles and capillaries. Digitalis in this condition is objectionable, and vasomotor dilators can be used only to tide over temporary great danger. Real treatment consists in reestablishing the function of the kidneys.

Dr. J. E. Winters regards the amount of albumin in the urine in subacute nephritis as the chief indication of the progress of the case, and he regulates the diet so as to reduce its quantity, giving little albuminoids.

Dr. Laurence Johnson spoke of the excellent results obtained in uremia, manifested in coma and convulsions, from the use of pilocarpin, and said no evil effects had followed in patients of good general condition.

The President said he always took into consideration the age, predispositions, and habits of his patient before commencing treatment. The management called for in children manifestly differs from that called for in adults. In acute Bright's disease the rule calls for rest in bed, room of even temperature, regulation of the diet, moderate purgation. Arterial tension should be reduced by drugs acting on the vasomotor system. This is best effected in his experience by calomel in small doses, accompanied by salines. Further measures consist of irritation over the kidneys and stimulation of the surface of the body.

In subacute nephritis the patient should not be depleted by any method whatever. The nutrition should be improved. Iron in these cases seems to be of little value. If digitalis increased the urinary excretion it would prove of value; otherwise, it would do harm. It is contraindicated in arterial tension. Small doses of opium are of marked value, and can be long continued in patients with weakened heart from accumulation of poison in the system.

Dr. Delafield remarked that iron might prove of benefit, and the benefit be manifest not in reduction of dropsy or effects on the quantity of urine, but in an increased number of red blood cells and of hæmaglobin.

The President stated that the Academy had secured a plot of ground, seventy-five by one hundred feet, just west of Fifth Avenue on Forty-third Street, and that it was proposed soon to commence the new building.

Reports of Clinics.

PENNSYLVANIA HOSPITAL.

MEDICAL CLINIC.—PROF. LONGSTRETH.

Diabetes. Fallacies of Some of the Tests for Sugar. Remarks on Diet and Methods of Treatment.

This young woman, 20 years old, was admitted to the wards three days ago. She is a seamstress. In her family history we find that kidney diseases occupy a very prominent place. Her father and two uncles were afflicted with Bright's, and her mother, also, seems to have been a victim of that disease. The patient says that she herself was fairly healthy until within a year ago. She then began to complain of pain in her back, her bowels were sluggish, and she had some uterine trouble. The commencement of her present illness dates from last July. At that time she first noticed that there was a large increase in the quantity of urine she passed. Thirst was somewhat more frequent and her appetite became enormously sharpened. Five or six meals in the twenty-four hours were barely sufficient to satisfy it. In spite of this heavy consumption of food, her strength rapidly declined. She did not lose much in weight, but she became unequal to even ordinary exertion. Her eyes then gave her some pain, there was a dimming of vision, and she was compelled to relinquish her sewing. These eye symptoms have now, however, passed away. There was a moderate evening rise of temperature and marked flushing after meals. Sleep was disturbed. She did not complain of pain at any time, but there was a more or less constant sense of fulness in the epigastrium.

On admission the girl seemed well nour-

ished. There was no perceptible dryness of the skin. The tongue was clean, but abnormally red. Pulse rapid. No organic lesions could be discovered, examination of the lungs, heart, liver, etc., being negative. The abdomen was full, but not tympanitic. She has now been under observation three days. Immediately after her admission she passed 32 ounces of urine, and during the ensuing twenty-four hours 120 ounces. Its specific gravity was 1042, slightly acid. The acidity of urine varies with its degree of dilution. If, with a normal proportion of salts, we have a largely increased bulk of fluid, the acidity will naturally be much lessened. An alkaline diabetic urine is of unfavorable significance. It indicates as a rule the occurrence of extensive tissue changes, these being principally located in the liver.

In carrying out the various tests for sugar, grave errors, unfortunately, are by no means infrequent. The reduction tests are often rendered unreliable by the fact that urea or urates are sometimes capable of reducing both copper and bismuth. There will form a dirty yellow precipitate which is frequently mistaken for the brighter brick red precipitate which is characteristic of the presence of sugar. Many cases are treated as diabetes which have been falsely so diagnosticated. Some years ago the late Prof. Wallace sent me for examination several specimens of urine which, I found, were free from any trace of sugar. Yet the patients from whom these specimens came, had been placed upon a diabetic treatment on the testimony of a chemist who erroneously thought that he had discovered in them a greater or less quantity of sugar and had so reported to Dr. Wallace.

Of the different tests for sugar, I think that by fermentation is the best. Several apparatuses have been devised for conveniently carrying it out. This one that I show you is very simple and sufficiently accurate (Einhorn's saccharometer). It consists of a bulb connected with an upright tubular arm, one side of which is graduated to the volume of carbonic acid gas in cubic centimetres, while the other shows the percentage of sugar. Its capacity is 10 c.c. A gramme of compressed or any other variety of yeast is added and with a little heat fermentation quickly occurs. With regard to the treatment of these cases, an accurate knowledge of the amount of sugar given off by a diabetic, whether large or small, is not of so much importance, as is a knowledge of the rate by which it is being reduced from day to day. This will indicate most clearly whether the measures you have adopted are or are not proving effective.

In taking up the treatment of diabetes, I wish to call your attention to one of the newer of the many remedies that have been proposed for that disease—nitrate of uranium. It has been used in this case with apparent good effect, the amount of sugar passed having been consideraly reduced. It is given in the dose of one grain three times daily, in pill or powder. An addition of nitric acid is required to effect its solution, and, therefore, this is not a desirable form in which to administer it. I have not instituted as yet any change in the patient's diet. Personally, I disapprove of the very abrupt changes of diet to which these patients are commonly subjected. The diet lists usually prepared for diabetics, are much too rigid, I think, for sudden enforcement. A gradual reduction of the hydro-carbonaceous elements of the food is much more likely to be favorably borne than a sudden deprivation of them. The system suffers more or less shock when it is abruptly deprived of such an important class of materials as these. It is more prudent to strike out the sugars and the purer starches first, and then by degrees to cut them off, if necessary, altogether. Instead of immediately forbidding all kinds of bread, let the patient limit himself for a time to the bran breads. While eliminating the starches it is a good plan to add the fats. These are especially useful when there is any tendency to constipation. Butter and cream may be used in such cases with benefit. The human body requires a certain amount of variety in food. We are not made up of bread and butter, for example, and we can hardly expect, therefore, to maintain a man's health and capacity for labor on any such slender supply of nourishment. My first order, generally, to victims of this disease is, that they shall eat only such vegetables as grow *out* of the ground, and give up those that grow *in* it. Of course, such articles as rice and beans are excepted from this rule, which, I think you will find, is a fairly good one.

Now, let us, for a moment, ask ourselves why this woman should have diabetes. What has occurred to give rise to it? This disease may be dependent upon a variety of causes. In this case, where we detect some digestive disturbance, I think the liver is chiefly at fault. For some time previous, the bowels were inclined to be inactive, digestion was imperfect, and, through defec-

tive assimilation, the normal proportion of sugar in the blood became gradually increased. While, in treating these cases, it is well enough to endeavor to reduce the amount of sugar appearing in the urine, still it must not be supposed when that point is gained, that the disease itself is conquered. Our chief object should be to bring about such a state of the assimilative functions that our patient, with ordinary attention to the special rules of health operating in his or her case, may live comfortably without provoking a return of the disease. The first symptoms complained of by this patient drew our attention to the condition of the abdominal circulation. It was inactive. The liver was too fully charged with blood to perform successfully its secretory functions. In time we should have had obstinate constipation with a marked deficiency of biliary salts in the stools. To avoid this, and, at the same time, to prevent the occurrence of any permanent change in the liver, the portal circulation must be stimulated. The intestinal evacuations should be as carefully examined as to the presence of sugar and bile salts, as are those from the kidney.

In studying the treatment of diabetes in this country we have largely confined our attention to the regulation of the diet. In doing this we have overlooked the claims to consideration of certain natural and easily obtained remedies. In England and on the Continent the waters of some of the springs there, are used almost exclusively in the treatment of this disease. The Carlsbad waters are probably the most efficient of those in common use. We no longer however have to send our patients abroad in order to obtain them. We now receive the natural water in glass, and, in addition, the Sprudel salt in powder form. The Carlsbad water on cooling throws down an excess of salts which it contains when drawn directly from the springs. By artificially warming the water and adding a sufficient quantity of the Sprudel salt, we can restore to it its original proportion of saline constituents. This water should be consumed in moderate quantities only. The best effect upon the liver is not to be obtained by the production of violent catharsis. A comparatively gentle action will quickly show beneficial results in the improved character of the stools. The most valuable constituents of the various laxative mineral waters, are the chlorides. It is when these are present in large quantity that a water acts most vigorously as an hepatic stimulant. The treatment already instituted in this case will be continued. One of the chlorides, if necessary, will be added to the uranium, and the diet will be gradually reduced to the requisite degree of rigidity.

[A few days later, without premonitory symptoms, the specific gravity and the quantity of sugar showed unusual oscillations without the quantity of urine secreted daily changing to a marked degree. A microscopic examination of the urine showed blood corpuscles, and blood and granular epithelial casts, which were not present on the patient's admission.

The terminal symptoms were ushered in by violent abdominal pain, especially in the lower epigastric region. The relief was with difficulty obtained by anæsthetic inhalations and morphia. To this condition succeeded gradually increasing stupor and finally coma, with reduction but not complete suppression of urine. No amelioration was effected by hot-air baths or by pilocarpine hypodermically administered. Death came by respiratory failure.

The *post-mortem* examination showed a swollen fatty liver, much congested, and thick dark green bile in the gall-bladder; the kidneys swollen, with the tubular epithelium opaque and granular; no other organic disease.]

BELLEVUE HOSPITAL, NEW YORK.

GYNECOLOGICAL CLINIC—PROF. POLK.

Pyosalpinx.

Prof. Polk operated for pyosalpinx in a patient, 35 years old, whose chief symptom was persistent pain. The disease was of several years standing.

On opening the abdomen the uterus, tubes and ovaries were found matted firmly together in a circumscribed mass. The left tube and ovary were adherent to the pelvic floor, and also to the rectum. The left ovary was enlarged and contained pus; and the tube was also distended with pus. On the right side, the ovary was very tightly attached to the rectum; the tube was twisted on itself, enlarged from pus, and adherent to the ovary.

By slow dissection with the fingers (the assistant pressing up the uterus with the fingers in the vagina), familiarizing the touch as well as possible with the different tissues, Prof. Polk isolated the left ovary and tube and removed them. The right ovary was so firmly adherent to the bowel that its removal meant almost certain laceration of

that viscus; it was, moreover, hard and evidently contained no pus; it was therefore allowed to remain. The corresponding tube, which was distended with pus, was separated with considerable difficulty from its plastic relations, and removed.

The seat of the operation was flushed with carbolized water; the peritoneum sewed with continuous catgut sutures; a glass drainage-tube inserted in the inferior angle of the wound (to be removed in 24–48 hours, if possible); the fascia, together with the abdominal wall, sewed with interrupted silk sutures; iodoformed lint and gauze laid on, in layers; and a wad of antiseptic cotton applied under a binder.

Prof. Polk remarked that these were the sort of cases he would formerly have refused to operate upon. But of late his views have changed in this regard. And, although the operation had lasted nearly two hours, he believed the patient's chances of recovery about as good as after an ordinary oöphorectomy. He said it would surprise him very much if the patient were to die.

The operation could have been much more quickly performed had the old method of procedure been followed; namely, a longer incision, and the removal of the intestines from the pelvis and placing them upon the abdomen (there covered with hot wet towels), to permit of inspection as an aid in separating the adhesions. But the result would be, almost certainly, a fatal termination to the case. It makes a vast difference whether adhesions are of years' or of months' standing. Old adhesions, such as were present in this case, bind the viscera so closely together that it is almost impossible to distinguish one tissue from another. And it is only by the slowest and most careful procedure that separation may be safely accomplished. Had the right ovary been found to contain pus, he would, nevertheless, not have attempted its removal, but would have laid it open, washed it out, and inserted a drainage-tube into it.

—The *Boston Med. and Surg. Journal*, Feb. 28, says: From a report laid before the Dominion Parliament, it appears that there are at present nineteen lepers confined in the Dominion lazaretto at Tracadie, New Brunswick—eight males and eleven females. During the year two new patients were admitted from the surrounding country. Last year one of the male lepers escaped from the institution to the United States, where he has been located by the Dominion officials.

BOSTON CORRESPONDENCE.

(FROM OUR OWN CORRESPONDENT.)

Progressive Muscular Atrophy.—Supra-pubic Prostatectomy.—Chronic Arsenical Poisoning, especially from Wall-Paper.

BOSTON, March 11, 1889.

At the last meeting of the Boston Society for Medical Improvement, Dr. Philip Coombs Knapp showed a case of progressive muscular atrophy, the most interesting feature of which was the man's age, viz., sixty-eight years, since it is a very rare thing to find this disease coming on so late in life. Reference was made to Gowers, who says that progressive muscular atrophy may come on at various periods until seventy years of age; but during this latter period it is surely very rare. In the case exhibited, the appearance of the disease dated back only about six months. It commenced with a wasting and numbness of the hand. The reaction of the muscles showed the ordinary changes of degeneration. There was no sensory disturbance to be made out, and the probable onset of bulbar disturbance made the case quite clear. There was no difficulty of swallowing and no exaggeration of the reflexes.

Dr. F. S. Watson reported a most interesting case of profuse hæmaturia, in which the operation of supra-pubic prostatectomy was performed, followed by recovery. The patient, whose age was sixty-nine years, had been in excellent health until ten years previously, when symptoms of urinary obstruction due to hypertrophied prostate appeared. The use of a catheter kept him comfortable until about three years ago, when there was blood in the urine due to profuse hemorrhage into the bladder. During the next two years he had two or three other attacks of bleeding, since which they have been more frequent, occurring latterly about once in two months. The attacks were characterized by the loss of a large quantity of blood at the onset, then there was a diminution in the quantity during the following days, until, at the end of about a week, the urine was quite clear. The hemorrhages were independent of exertion and there was no pain, excepting from the retention of clots and over-distention of the bladder. The patient thought he had noticed fleshy bits in the urine, and he stated that an eminent physician in New York had told him that a villous growth could be plainly seen through the cystoscope.

When the patient first visited Dr. Watson he was very anæmic and weak from the effects of a hemorrhage that occurred about a month before. Although examination of the urine for several days failed to detect any positive evidence of a bladder tumor, the hemorrhages were undoubtedly of bladder origin; and, moreover, they were increasing in severity and occurring at diminishing intervals, so that they pointed to a fatal termination. On this account an operation was determined upon, and as the patient had an hypertrophied prostate, together with a large and distensible bladder, it was decided to open the bladder above the pubes. The cystotomy was performed in the manner recommended by Petersen. When opened the inner surface of the bladder was found to be entirely smooth and no villous or other growth was present, except the projecting lateral portions of a greatly enlarged prostate. They were connected by a less prominent median ridge, which, sometime previously, had been perforated by an instrument about half way from its base, and, about this hole were flabby and exuberant granulations. The lateral lobes of the hypertrophied prostate were divided into halves by a blunt bistoury, and each portion was removed to its base by a wire écraseur. The median portion was then removed with scissors and the curette, thus clearing away the granulating surface. The wounds were left open and a large, double, rubber drainage tube was placed in them, reaching to the bottom of the bladder. There was little hemorrhage, either during or after the operation, and it ceased on the fourth day.

This operation was performed three months ago—and there has been no hemorrhage since. With the exception of one or two attacks of heart failure the patient had a good convalescence, and went home at the end of six weeks from the date of the operation. The peculiarity of this case is that the hypertrophied prostate simulated in its symptoms bladder growths.

Dr. Watson thought that an attempt at removal by operative procedure should be made if a diagnosis of a bladder tumor, probably benign, is made. If, however, the tumor is believed to be cancerous, it had better be left to itself if it is not attended with pain; but when there is much pain associated with it, palliative measures by drainage should be attempted. Quoting from his own writings, Dr. Watson said that advice as to operative interference in cases of prostatic hypertrophy should be based upon the following indications: "Necessary, frequent (once an hour), painful catheterization, or urination without the catheter, especially when accompanied by a foul or hemorrhagic cystitis; attacks of retention; and failure to relieve such condition by palliative treatment."

The notes on twenty-five cases in which arsenic was found in the urine formed the basis of a most interesting contribution on chronic arsenical poisoning, especially from wall-paper, by Dr. James J. Putnam. In this paper he said that the time has nearly gone by when fair-minded persons, who have taken pains to investigate the evidence, need to be convinced that arsenical wall-papers and fabrics may be a source of poisoning. The problems of chief importance at present are: how we may learn to recognize with greater confidence the less typical cases; how we may persuade our legislators to give us due protection against this widespread public danger. It has been asserted by our chemists that the dangers from these sources are by no means so great as formerly, but it is evident that they are still far from being obviated. Acute arsenical poisoning has long been familiar to toxicologists, and the subacute form is usually easily recognized; but in the chronic varieties we have only the shadows of these characteristic symptoms to guide us; and, moreover, we may be led astray by the fact that the arsenic may only act by bringing out the latent weaknesses of the patient. The most convincing symptom is neuritis of a sufficiently advanced degree as to cause changes in electrical reaction, diminution of cutaneous sensibility, and impairment of motor power or of coördination. Another important physical sign is a peculiar browning of the skin, especially of the face. Still another important sign is albuminuria, with casts and sometimes blood in the sediment. Cerebral symptoms, such as vertigo, impairment of memory and mental endurance, and rarely epileptiform seizures, are met with in cases of chronic arsenical as in lead poisoning; and they may be suggestive, if not characteristic, if other causes can be excluded.

Dr. Putnam then gave in detail the history of certain cases that had come under his observation, and especially the case of a woman forty-three years of age, naturally of good health and habits. The symptoms pointing toward possible chronic arsenical poisoning, the wall-papers were examined and a large quantity of arsenic was found in two of them, which covered the walls of three rooms. The largest amount was found

in the room used by the patient as a bedroom. A month later the urine of the patient, on analysis, was found to contain a very large quantity of arsenic. After various vicissitudes in cleaning lodgings and wall-papers there was, some months later, a marked improvement in the symptoms; but the continued presence of arsenic in the urine rendered it probable that the poison was still given off from sources still accessible.

A most interesting discussion followed this paper, and among other speakers Dr. Edward S. Wood, the expert in toxicology, said he thought the only way we shall ever be able to get a law restricting the sale and manufacture of arsenical wall-papers, is by being able to bring forward a large number of accurately reported and well-authenticated cases of arsenical poisoning, in which there is no doubt whatever as to the presence of arsenic in the system, and when we are able to state accurately, or at any rate within narrow limits, the amount of arsenic in a wall-paper which has proved dangerous. Dr. Wood thinks it is very difficult to make any accurate statement in regard to the time of elimination of the arsenic. There are certain cases which seem to show that it requires six or eight months for arsenic to be entirely eliminated from the system. The number of sources for the absorption of arsenic is so great that it is very difficult to say when all of the sources of poisoning have been entirely removed. This seems to him a fair explanation of the continuation of the arsenic in the economy in some of these long-continued cases.

PERISCOPE.

Three Remarkable Cases of Actinomycosis.

Bertha reports from Wöfler's Clinic at Graz to the *Wiener med. Wochenschrift*, No. 35, 1888, three cases of actinomycosis, which are interesting both from the seat of the disease and the mode of infection. It is highly probable that in all three a direct infection of the person was received through the actinomyces clinging to grain, while we are usually accustomed to consider animals affected with actinomyces as the agents of the infection.

In the first case, a laborer, 52 years old, in the act of drinking, swallowed the beard of an ear of corn, which stuck in his pharynx. An inflammatory affection of the throat resembling an abscess developed, but apparently healed after surgical treatment; after three years, however, it relapsed and was recognized as actinomycosis. In both the other cases, there was an actinomycotic affection of the hands in persons who handled grain.

Such localized actinomycotic affections on the hand and leg have been described only once hitherto in literature, but in Bertha's opinion are not so very rare; they have often been erroneously regarded as lupoid or tuberculous.—*Centralblatt f. d. med. Wissenschaften*, Jan. 12, 1889.

Relation of Purpura to Malignant Disease.

The causation of the purpura which has been noticed in connection with malignant disease, especially sarcoma, has not yet been satisfactorily determined. With the view of throwing some light on the obscure subject, Dr. Thomas Harris communicates to the *Medical Chronicle*, Feb., 1889, an account of a case in which he had occasion to make an autopsy. The patient was a young man who had died a few hours after admission to the Manchester Royal Infirmary. The body, a fairly nourished one, was markedly anemic. All over the trunk and limbs were a large number of petechial hemorrhages into the skin. In the mediastinum was a tumor the size of a goose-egg, apparently a firm lymphosarcoma. The right pleura showed signs of what appeared to be acute inflammation, and the cavity was distended with a quantity of thin blood. Petechial hemorrhages were present in the stomach, intestine, peritoneum, and pericardium. The spleen was increased in size, weighing eight ounces, and was of a pale-red color. No growth except the one in the mediastinum was evident to the naked eye, and the chief change from the normal presented by the organs throughout the body was one of anemia.

After giving some of the cases observed by the late Dr. Hilton Fagge, he discusses the theories as to the causation of the purpura, especially in his own case. He rejects the view that there might have been minute developments of sarcomatous tissue, with growths made up of embryonic cells at points which became the seats of the petechiæ. He also is disinclined to believe that the malignant disease had caused a profound alteration of the blood, analogous to that found in pernicious anemia, and that the hemorrhages were due to this. For a

microscopical examination of the liver, and especially of the kidneys, showed that in those organs there were emoboli, composed of minute masses of tissue similar in appearance to that composing the mediastinal growth. Although he found no emboli in the vessels of the skin, he nevertheless regards the purpura that occurred in his case as due to emboli lodging in the small vessels.

Prevention of Phthisis.

Dr. J. E. Squire read a paper on prevention of phthisis before the Epidemiological Society of London, January 9, 1889. He said that phthisis took its place with bronchitis as one of the most frequent causes of death in this country, and its importance is the greater as it carries off its victims during adolescence and adult life. The discovery of the bacillus tuberculosis allows us to place phthisis in close relation to infectious diseases, toward the control of which preventive medicine has already done so much; and experiments have proved that tubercular disease can be communicated from affected to healthy animals. That consumption can be communicated from person to person has long been a popular belief, and cases were referred to by Dr. Squire which seemed to prove it. Phthisis depends primarily upon the reception into the body of an infective particle or micro-organism; but a lowered vitality of the tissues places them in a more favorable condition for the development of the bacillus, and thus constitutes in the individual a predisposition to the disease. The bacillus may gain entrance into the body (1) by inoculation through a cut or scratch; (2) by means of the genito-urinary mucous membrane; (3) by the product of conception, and by direct hereditary transmission; (4) by the mucous membrane of the alimentary canal; (5) by the mucous membrane of the respiratory tract, and by the air-cells of the lungs.

The possibility of infection through the alimentary tract assumes importance from the prevalence of tuberculosis in animals which are used as food, and from the experimental proof of the infectiveness of the milk of tuberculous cows. The necessity for careful inspection of cattle kept for dairy purposes and for precautions in using the milk, and possibly also the flesh of diseased animals was pointed out. But as infection through the respiratory system is more potent and probably more frequent than by any other means, and as the risk of infection is intensified by close contact and by the crowding together of sick and healthy, the necessity for free ventilation is apparent, and becomes more so when the predisposing causes are considered. These are: (1) hereditary predisposition; (2) influence of air and sunlight; (3) age and sex; (4) effect of certain occupations; (5) influence of locality and habitation, which includes the consideration of climate, temperature, altitude, nature of the soil, density of population, and the condition of dwelling-houses, both as to their construction and the overcrowding of the inmates; (6) influence of certain diseases, local and general. Indoor and sedentary occupations, as well as those in which much dust is inhaled, largely influences the prevalence of phthisis. Much of this amongst persons following such occupations is preventable. Here again the basis of all preventive measures is found in efficient ventilation. The home-workers—for example, tailors—are more difficult to deal with than the factory hands; but public workrooms, in which men can find conveniences for their work, may lessen the evils of the present state of things. With regard to climate, its influence in the causation of phthisis is probably infinitesimal as compared with the effect of density of population. Overcrowding is of two kinds: the aggregation of buildings on a confined area, with insufficient open space around and between houses, and the crowding together of persons within the houses.

By-laws should be enforced regulating the width of streets, the amount of open space around houses, the minimum height of rooms and size of windows, and efficient inspection of new houses should be carried out before they are allowed to be occupied. Tenement houses might be licensed to hold a certain number of inmates, and be liable to inspection. As many diseases producing general debility thereby predispose to tuberculosis, general sanitary and hygienic measures, framed for the control of these, tend to diminish the amount of phthisis in a community; and seeing that insufficiency of food, of fresh air, and of exercise, continued anxiety and mental depression, and dissipation, must be reckoned amongst the predisposing causes, the philanthropist might assist the sanitarian. The fundamental principles which must form the basis of any successful attempts to diminish the prevalence of phthisis are (1) to provide a sufficiency of fresh air in and around dwellings and workplaces; and (2) to endeavor

to improve the resisting power of the individual by physical training during the period of growth and development, and by exercise and recreation alternating with the work of maturer age. As the effects of phthisis are handed down by hereditary transmission from parent to child, any causes which tend to increase tubercular disease amongst the adult members of a population must be regarded as tending to produce a progressive deterioration of race. It is, therefore, to the interest of the community to allow no time to be lost in commencing a systematic attack against the preventable causes of phthisis.—*British Med. Journal,* Jan. 26, 1889.

Spinal Hemorrhage with Pyrexia.

Before the Staffordshire Branch of the British Medical Association, Nov. 30, 1888, Dr. Arlidge related a case of hemorrhage within the sheath of the spinal cord, attended with high temperature. The patient was a well-built and well-nourished man, but of drunken habits, 44 years old. He was admitted into the North Staffordshire Infirmary on September 19 last, having four days previously been suddenly seized with complete loss of power over his legs. The attack was preceded for a day or two by a slight feeling of *malaise,* but he had never been laid up with serious illness, and never had syphilis or rheumatism, nor had he suffered any hurt to the spinal column. There was complete motor paralysis of the legs, and some weakness in the arms, where too formication and numbness were experienced. Sensation was normal, and the legs were painless and their reflexes abolished. His only complaint was of dorsal pain. The bladder was distended, and, prior to admission, had been emptied by the catheter, but there was no dribbling of urine. Some rhonchi were noted in the upper part of the left lung; heart healthy; bowels confined for four days; the cerebrum undisturbed. The first temperature taken was 103.6°, but the next day it fluctuated between 105° and 106°, and rose to 107.4° the day preceding his death, on September 26, and was accompanied by some delirium. A post-mortem examination revealed a copious hemorrhage within the meninges of the spinal cord, extending downward from the last cervical vertebra for about six inches. The blood was coagulated. No ruptured vessel was found in the cord itself, and no cerebral disease, although the dura mater was very adherent to the skull. There was no fracture of the spine, and no caries of any vertebra. Dr. Arlidge called attention to the suddenness of the onset of the paralysis and the high temperature, the former phenomenon being characteristic of spinal hemorrhage, whilst the latter was an altogether exceptional occurrence. Other points of interest were the stillness of the paralyzed limbs, their freedom from spasm, and likewise from hyperæsthesia and anæsthesia alike; and, lastly, the absence of any physical injury, or of evident antecedent spinal lesion, to account for the production of the hemorrhage.—*British Med. Journal,* December 22, 1888.

An Unusual Cause of Asthma.

Professor Leyden had recently under treatment a young woman who suffered from extremely irritable cough, with some pain in the neck. The diagnosis he made was that of bronchial catarrh combined with asthma. The remedies he prescribed were of little use. He then sent the patient to Schwalbach, but this also proved of no avail. It was then proposed that she should spend the winter in a warm climate, when she appeared one day with the gratifying intelligence that she was now quite well. Upon drinking a cup of tea that morning she was seized with an exceedingly violent fit of coughing, so that she thought she would have been choked. Suddenly, however, she coughed up a small portion of bone, and having got rid of that her cough was at an end. It seems that some eight or nine months previously she swallowed a piece of bone while eating, which caused a most violent attack of coughing. She immediately sought the aid of a medical man, who passed a probang, but found nothing. Ever since that time she had suffered from the cough and from severe pains in the throat, for which she ultimately consulted Professor Leyden. It is impossible to say exactly where this splinter had lodged, but having sharp points, these were probably embedded in the mucous membrane of one of the bronchi. A somewhat similar case is mentioned as having occurred under the care of Professor Bardeleben in the Charité, Berlin, where a case of persistent hoarseness was found after death to be accounted for by the lodgment of a coin (a one-mark piece) below the right vocal cord.—*Lancet,* Feb. 16, 1889.

—Diphtheria is prevalent in the neighborhood of Macungie, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

HEAD-DOWNWARD PRESENTATION.

The remarkable fact that in about ninety-six per cent. of cases of labor the fœtus is born head first has attracted attention since the days of Hippocrates, and doubtless long before. Nor is it less striking that in about seventy-five per cent. of labors the child should assume one relation to the mother—that the fœtal occiput should be in relation with the left anterior segment of the mother's pelvis. The oldest known theory in explanation of these facts is that of Hippocrates, which supposes that the fœtus is originally head uppermost in the uterus, where it is held by bands proceding from the umbilicus until the seventh month, the legal time of labor, when these bands break, and the fœtus, from its own weight, turns a somersault, and so places itself head-downward. Ambroise Paré asserted that the fœtus instinctively placed itself head-downward because delivery is easiest in that position. Paul Dubois, after satisfying himself that the fœtus does not present head downward because of gravity, since the centre of gravity of the fœtus is not situated in the head, but at a point in the trunk near it, returned to the theory of Paré, that the fœtus, by instinctive or voluntary determination, makes certain movements until it finds the position most favorable for its sojourn in the uterus, and for its delivery from it. Simpson denied that the fœtus is able to make voluntary movements; and declared that the attitude of the fœtus is produced by reflex movements induced by a lack of relation between the contour of the fœtal ovoid and the containing uterine walls; that after the seventh month of pregnancy both the fœtus and womb are ovoidal in form, the wide end of the fœtal ovoid being at the breech, the wide end of the uterine ovoid at the fundus; and hence that irritation and reflex movements ensue until corresponding diameters of each come into relation with those of the other, when irritation ceases and the presentation becomes fixed and definite.

Matthew Duncan still insists that the attitude of the fœtus *in utero* is produced by the laws of gravity, and he offers elaborate explanations of various facts which apparently conflict with this view. Credé, Kristeller and others attach much importance to the intermittent contractions of the uterus throughout pregnancy, as a cause of the attitude of the fœtus. Pajot considers the form of the matured ovum, the dimensions of the uterus, and the fact that it is alternately in a state of motion and repose, as the determining causes of the attitude of the fœtus.

Other and less celebrated theories have

been offered, until, as Charpentier says, there are explanations enough, but unfortunately there are objections to each.

In the *Edinburgh Medical Journal*, September and October, 1888, Dr. James Foulis contributes an interesting and elaborate paper on the cause of head-downward presentation and the first cranial position. He reviews the theories of Simpson and Duncan, points out the objections—more especially to the theory of Simpson—and rejects them both. The principal objection which is urged against the theory of Simpson is his assumption that the uterus has a fixed and definite form independent of the form of the fœtus—spheroidal before the sixth month, and ovoidal after that time.

Dr. Foulis asserts that the head-downward presentation of the child *in utero* is the necessary and ultimate consequence of the continued extension of the child's lower limbs against the most resisting parts of the uterine sac. Before the seventh month, and to a certain extent after this time, when the fœtus has a considerable amount of mobility within the uterus, extension of the child's legs must drive the head along the surface of the uterine wall; and since the feet meet with the firmest resistance from the maternal pelvis, the ultimate consequence of the movements must be to bring the head downward, which position is maintained in the later weeks either by the straitened room of the fœtus limiting its mobility, or by the head entering the true pelvis as a ball in a cup.

Dr. Foulis maintains that the first cranial position is produced by the continued extension of the child's lower limbs against the most resisting part of the uterine sac at its upper part—namely, that which lies in the right hypochondrium, under the liver—after the child has assumed the head-downward position.

The arguments of Dr. Foulis are certainly ingenious, and are apparently based on that foundation of medicine, anatomy; but we are not convinced that his explanations are truer or his arguments better than are those which he seeks to overthrow. It seems plain that the attitude of the fœtus in its relations to the mother, is produced by no one cause, but that it is the result of the combined action of several causes; these are: the form of the matured ovum, the dimensions (its shape being variable) of the uterus, gravity, the intermittent contractions of the uterus, the varying amount of liquor amnii, and the movements of the fœtus—all of which usually act in harmony to bring about the head-downward presentation of the fœtus. Other presentations occur under unusual conditions, as when the relation of the diameters of the uterus is altered by flaccidity of its walls, or by deformity of the pelvis; when its axis is altered by relaxation of the abdominal parietes; when the form of the fœtus is abnormal, as in hydrocephalus; or perhaps when an ill-timed, vigorous, extension of the child's legs produces other than a head presentation, which altered presentation becomes permanent owing to the straitened room of the fœtus, which limits subsequent mobility.

The writer's argument that the first cranial position is most frequent because the child's lower extremities meet with more resistance, in extension, in the right upper segment of the uterus—owing to its location under the liver—than in the left upper segment, and hence that the dorsal region of the child is pushed over to the left, is not so happy. How on this ground can it be explained that the position second in frequency is the very reverse of this—occiput to the right and posterior? The usual explanation is more satisfactory.

But while his conclusions may not be accepted, Dr. Foulis has presented an ingenious explanation of the result of the movements of the child in utero; and his scholarly paper has called the attention of the profession anew to the subject of the accommodation of the fœtus—one of the most interesting problems in physiology.

HOSPITAL TREATMENT.

There is an impression, quite general among the poor, that entrance into a hospital as a patient involves the risk of becoming the subject of experimentation by the physicians and surgeons connected with the institution. This is especially the case in regard to hospitals connected with medical schools; and very recently an English writer who takes the name of Æsculapius Scalpel has done what he could, in a book called "St. Bernard's," to confirm this impression where it exists, and to create it where it has not already taken root, by describing the experiences and observations of an assistant in a large hospital. The scenes described in this book are too real and too like the truth to be scoffed at as wholly untrue, although the way in which they are used is unfair and unjust. There can be no doubt that the author is one who has walked the wards of an English hospital, and has witnessed occurrences which seemed to him cruel and unfeeling. No one who has seen much of hospitals in any land can deny that operations are sometimes performed in them with apparently less regard for the good of the patient than the eagerness to seize opportunities for demonstration. Nor can any one who has studied physical diagnosis much have failed, we believe, to have seen cases in which persons weary and worn with disease have been subjected to examinations too repeated and too prolonged for the benefit of students.

It is not altogether amiss, then, for those who pursue science ardently to be reminded that those whom they find interesting subjects of investigation have feelings and rights which ought to be respected; but it is far from right for an author to sanction the idea that hospital doctors, as a rule, disregard these feelings and rights. In this country, certainly, the men who have charge of hospital patients are not generally unfeeling; and those who are under their care usually enjoy the blessing of skilful treatment combined with humane consideration to an extent which more than counterbalances the unavoidable disadvantages of their situation.

BEQUESTS OF ISAIAH V. WILLIAMSON TO MEDICAL CHARITIES.

In the will of the late Isaiah V. Williamson, of Philadelphia, who died March 7, 1889, leaving an estate valued at about ten millions of dollars, the following bequests of interest to medical men were made: To the Pennsylvania Hospital $100,000; $50,000 each to the Episcopal Hospital, the University of Pennsylvania and the University Hospital; $40,000 each to the Children's Hospital, the Women's Hospital, the Orthopædic Hospital, and the Woman's Medical College. The testator expressed the desire that these sums should be invested by the recipients, and he directs that the income shall be expended for the establishment of free beds only. By this it is probable he meant the maintenance of free beds, as the invested funds would serve to establish them.

One of the items of this will directs the investment of $300,000 by trustees, who are directed to pay five per cent. of the income —which would be about $500 annually—to the Philadelphia Lying-in Charity. Three per cent., or about $300 a year, is to be paid to the Philadelphia Dispensary. Two per cent., or about $200 a year, is to be paid to the Northern Dispensary, and a like amount to the Howard Hospital (a dispensary) and to the Church Dispensary at Southwark—a portion of Philadelphia.

These bequests, with others to non-medical charities, make up a principal sum of a million dollars, and within a few months Mr. Williamson established a trust for a training school for boys, with a gift of $3,000,000.

In this way it will be seen that he has furnished another striking example of the way in which wealthy men in this country often use their wealth for the good of their fellow-men—a thing which has no adequate counterpart in any country in the world.

MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The Local Committee at Newport, R. I., decided some time ago, after consultation with some of the officers of the American Medical Association, to change the date of the next meeting of the Association, to be held at Newport, to June 25–28, because that date offered better opportunities for the entertainment of the members. Dr. Horatio R. Storer, Chairman of the Committee of Arrangements, has issued a notice stating that the general Sessions will be held at the Music Hall, Bellevue Avenue, adjoining the Ocean House, and those of the Sections at the Newport Casino, which is also close at hand, and which, for the first time in its history and as an act of courtesy, is permitted by its Governors to be occupied for other than the purpose for which it was built.

The hotels at Newport are, in order of their nearness to the place of meeting, the Ocean House, the Clifton House, the Germania Hotel, Pinard's, Hartmann's, the Aquidneck, Brayton's, the Kay Street House, the Perry House, the Park House, the Sherman House, the Cliff Avenue Hotel, and Bateman's.

The approaching meeting of the American Medical Association occurs nearly synchronously with the two hundred and fiftieth anniversary of the settlement of Newport. The city authorities, Dr. Storer says, will probably fittingly recognize the presence of the National Medical Convention at such a moment, the more cordially since the virtual founder of the colony, certainly its principal leader, John Clark, was a physician. The Mayor of the City was one of the incorporators, in 1879, of the Newport Sanitary Protection Association.

Members of the Association or others who intend to be present may get any information they may desire from any member, preferably the Chairmen of the various sub-committees, which are constituted as follows:

Of *Finance*, Drs. F. H. Rankin, H. G. MacKaye and G. D. Hersey; of *Reception*, Drs. H. E. Turner and G. M. Odell; of *Halls and Accommodations*, Drs. C. F. Barker and M. E. Baldwin; of *Entertainment*, Drs. S. H. Sears and T. A. Kenefick; of *Invitations*, Drs. W. C. Rives and G. T. Swarts; of *Registration*, Drs. H. Ecroyd, Jr., and W. S. Sherman; of *Exhibits*, Drs. C. A. Brackett and E. P. Robinson; of *Transportation*, Drs. P. F. Curley and W. H. Palmer; of *Section Work and Programme*, the Chairman, Dr. H. R. Storer, and the Local Secretary, Dr. Valentine Mott Francis. All of these gentlemen may be addressed at Newport, R. I., except Dr. Hersey, Dr. Swarts and Dr. Palmer, who live at Providence, R. I.

Members of the Association desiring to read papers should address the Chairman or Secretary of the various Sections, who were named in the REPORTER, March 2, p. 287.

It is hoped that the next meeting of the Association, which will be its fortieth annual meeting, will be a large and successful one, and that it will serve to cement anew the bonds of sympathy which ought to unite the profession in all parts of the United States.

PRESERVATION OF CHLOROFORM.

As many of the accidents which follow the administration of chloroform as an anæsthetic, are believed to be due to impurity, it is important to know the best means of preserving it from change after it has been manufactured. This subject has recently been discussed by M. Marty, in the *Archives de Médecine et de Pharmacie Militaires*, and he suggests that chloroform should be kept in bottles of yellow glass, with ground glass stoppers, which have been thoroughly cleaned and dried, and that to the chloroform should be added one thousandth part of its weight of pure and absolute ethylic alcohol.

—John L. Adams, who was undergoing a long fast, died March 13. He had entered upon his twenty-seventh day of fasting, and was greatly emaciated.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE YEAR BOOK OF TREATMENT FOR 1889. BEING A CRITICAL REVIEW OF THE PRACTICE OF MEDICINE AND SURGERY DURING 1888. 8vo, pp. viii, 344. Philadelphia: Lea Bros. & Co., 1889. Price, $1.25.

Those who are familiar with the admirable predecessors to this little book will be glad to know that the volume for 1889 is now issued. It contains a brief summary of the progress in therapeutics during 1888 and appears very promptly after the conclusion of the year it covers. If it were nothing but an uncolored summary, it would have its advantages, but it is far more; for the articles are prepared by men well known in this profession, and specially fitted for the task; and they bear the stamp of the individuality of each. In regard to the book before us, it is enough to say that it is calculated to maintain the excellent reputation of the series to which it belongs, and we wish it success equal to its merit.

EXPLORATION OF THE CHEST IN HEALTH AND DISEASE. By Stephen Smith Burt, M.D., Professor of Clinical Medicine and Physical Diagnosis in the New York Post-Graduate Medical School and Hospital, etc. Small 8vo, pp. xiii, 206. New York: D. Appleton & Co., 1889. Price, $1.50.

The author of this book, in his preface, states that it has been prepared in response to requests from members of his classes for a work which should embody his views; and his book indicates his familiarity with the wants of persons studying physical diagnosis. It is plain, practical and sensible. The style is pleasant, the teaching is sound, and the whole is beautifully illustrated with wood-cuts and photo-engravings. In looking over the book, we note with satisfaction that the author does not fall into the error of speaking of heart murmurs as if they were pathognomic, taken by themselves. This is a point of great importance in physical diagnosis; for serious and damaging blunders can be made if heart murmurs are not studied in connection with other signs of disease or health

In other respects this book will be found a trustworthy guide, and it may be heartily commended to the attention of our readers.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request stating where the notice was seen and *enclosing a postage-stamp.*]

226. Below Sea-level. Nature's Pneumatic Cabinet—High Altitudes of Southern California. By Walter Lindley, M.D., Los Angeles, Cal. From the *Medical Record* and the *Southern California Practitioner.* 12 pages.

227. Double Chorio-Retinitis with Partial Degeneration of the Optic Nerve, etc. By Charles A. Oliver, M D., Philadelphia From the *Trans. of the Amer. Ophthalmological Society*, 1887. 6 pages.

228. The Radical Cure of Varicocele, Attended with Redundancy of the Scrotum, Demonstrated by Time. By Morris H. Henry, M.D., New York. From the *Journal of the Amer. Med: Association*, Nov. 10, 1888. 12 pages.

229. The History of the Filaria Sanguinis Hominis, etc. By William M. Mastin, M.D., Mobile, Ala From the *Annals of Surgery*, November, 1888. 42 pages.

230. Inflation of the Stomach with Hydrogen Gas in the Diagnosis of Wounds and Perforations of this Organ. By N. Senn, M.D., Milwaukee, Wis. From the *Medical News*, August 25, 1888. 11 pages.

226. Dr. Lindley's first paper calls attention to that part of San Diego County in California known as the San Felipe Sink, or the Conchilla Valley, a basin about thirty miles wide and one hundred and thirty miles long and depressed below the sea-level, at its lowest point, about three hundred and sixty feet. This he thinks would be a sort of natural pneumatic cabinet and good for phthisical or asthmatic persons. Dr. Lindley's second paper describes the natural advantages of the San Jacinto Mountains in Southern California as a resort for persons affected with diseases of the lungs. The descriptions of the beauty and grandeur of these mountains are interspersed with incidental allusions to persons who have been benefited by residing among or on them.

227. The case described by Dr. Oliver was that of a boy, 12 years old, who in addition to the trouble indicated in that part of the title given above, had very curious lymph extravasations upon the retina of one eye and floating free in the vitreous humor of the other. The excellent description of these conditions is very much enhanced in value by two beautiful chromo-lithographs prepared from water color sketches made by Dr. P. N. K. Schwenk.

228. Dr. Henry is well known as an earnest advocate of excision of a portion of the redundant scrotum for the cure of varicocele—an operation first proposed by Sir Astley Cooper, revived by Dr. Edward H. Dixon, in this country, and adopted by Dr. Henry about 30 years ago. Dr. Henry has now operated in this way fifty-nine times, and thinks as highly of the operation as ever.

229. Dr. Mastin's pamphlet contains a full and scholarly summary of our knowledge of the filaria sanguinis hominis, with especial reference to the observations in regard to it which have been made in the United States, and its relation to chylocele of the tunica vaginalis testis. It is illustrated with three woodcuts, contains a table of thirteen cases seen in this country and concludes with a full bibliography of the literature of the subject.

230. Dr. Senn's pamphlet describes his experiments to prove that the method of inflating the intestines, which he demonstrated so brilliantly at the last meeting of the American Medical Association, could be applied to the stomach, to detect perforations, together with the account of a case in which he successfully applied it to the human subject. This paper is not only very interesting, but a so a valuable and instructive contribution to the literature of surgery.

CORRESPONDENCE.

Compound Fracture of the Skull.

TO THE EDITOR.

Sir: Burton Unkerfer, 13 years old, was kicked by a horse on the left side of his forehead over the eye. The wound was one and one-half inch long by three-fourths of an inch wide, and extended through the skin, bone and brain-membranes. The edges of the bone around the wound were almost as smooth as if they had been cut with a sharp instrument. The fragments of bone were driven through the membranes into the brain, and were completely covered with clotted blood and pulpified brain matter. The wound looked as though the bone had been removed. I began to examine the wound, and soon found that I could not do so satisfactorily without the use of an anæsthetic. I therefore called in consultation Dr. J. N. Ketcherside, who administered chloroform; and we then proceeded with great care to explore the wound and remove the fragments of bone. We did not quit until we were perfectly satisfied that every piece of bone had been removed. In all we removed seven pieces, the largest of which was about three-fourths of an inch long by one-fourth of an inch wide. All clots and contused tissues were carefully removed. We then allowed the patient to rally from the anæsthetic, dressed the wound with a solution of chlorate of potash, and left it open for twenty-four hours, covered constantly with cloths wet in the solution. I left bromide of potash and ergot to be taken every two hours, aconite to control fever if it should arise, and opiates to control pain if any should be felt. I visited him next day and found him doing well. The wound was therefore closed. At the time of closure the brain and edges of the membranes were protruding considerably, but I pressed them back and closed the wound up entirely, except one small place left open for drainage. Nothing of any morbid nature interfered after this except a small fungus growth, which was removed by gentle washings.

The patient entirely recovered, and at this time, two years since the accident, has all his former characteristics unmodified. All that is left to show that he was once hurt is the cicatrix. I attribute the success obtained in this case to the thoroughness with which the fragments of both bone and flesh were removed, and also to good after-treatment. One object should always to be in view in such cases, viz., to leave nothing in the wound to irritate the parts, and not be in a hurry to get through.

Yours truly,
S. M. HUNTER, M. D.

Hope, Kansas,
March 9, 1889.

Abortion, with Placenta Previa.

TO THE EDITOR.

Sir: At 9 o'clock on the evening of Feb. 10, 1889, I was called to see Mrs. S., 19 years old, five months advanced in a second pregnancy. During the preceding two weeks she had been troubled with feelings of general discomfort, but no symptoms of a definite nature occurred until the day on which I saw her, when irregular pains in the back and pelvis, accompanied with moderate hemorrhage, had been going on for several hours. Without making an examination, I informed her of the threatening miscarriage, and ordered one quarter grain of morphine, to be repeated in forty-five minutes if the pains and hemorrhage persisted. Cold compresses were applied to the hypogastrium, and the thighs were raised on pillows.

At 2 o'clock the following morning I was hastily summoned to see her, and found her experiencing hard expulsive pains with a small amount of hemorrhage. Examination revealed a bag of waters of considerable dimensions, low in the vagina. Having no suspicion of anything being abnormal, I ruptured the membranes without attempting to diagnosticate the presentation, and was considerably surprised to find nothing presenting, although an effort was made to crowd the womb down by external pressure, with negative result. Feeling assured that a continuance of the contractions would force the fœtus down sufficiently to enable me to diagnosticate the presentation in a short time, I sat down to await results. In less than three minutes blood began dripping from the bed. A hasty examination now disclosed an os dilated to the size of a silver dollar, with a placenta centrally implanted over it. A small portion was detached, and through the aperture I could distinguish nothing, owing to the high position of the womb. The pains were weak, but sufficient to produce severe flooding at each contraction, and the patient was rapidly losing strength, being almost pulseless in five minutes from the time when the membranes were ruptured. I hastily administered alcohol, ammonia, and ergot, and sent for assistance, meanwhile making pressure

on the cervix with my fingers in the vagina, thus checking flooding to a considerable extent. On arrival of assistance, in the person of Dr. Smith, the vagina was tamponed with good results; the flooding ceased, strong contractions set in, and in fifteen minutes an 8 inch fœtus was extruded. The placenta was delivered almost immediately afterward, and the case has since progressed well.

The peculiarity in this case was the large bag of waters low in the vagina in front of the presenting placenta.

Yours truly,

WILLIAM S. CARY, M.D.

Gothenburg, Nebraska,
Feb. 21, 1889.

NOTES AND COMMENTS.

Treatment of Scabies.

In a paper on the Increasing Prevalence of Scabies, with Remarks on Treatment, Dr. James C. White, Professor of Dermatology in Harvard University says that in sulphur, styrax or Peruvian balsam, and naphthol we have three effective, sufficient parasiticides. The action of the other substances employed so generally in combination with them, the alkalies, tars, gritty powders, etc., is simply auxiliary, and addressed to the solvent or mechanical removal of the epidermal coverings, or crusts, which protect the animals and eggs in the burrows and pits against the active agents; or these agents are intended for the relief or prevention of the inflammatory processes, which always accompany the disease, or may be provoked by the injudicious use of the remedies employed in its cure. It is in a proper knowledge of these latter, most essential, points of treatment that the successful management of scabies chiefly consists. It should never be forgotten, he says, that every case of advanced scabies is mainly an eczema, developed, in extent of surface affected and intensity of lesions, by individual peculiarity of the cutaneous tissues under the influence of scratching; and that the changes in the skin due to the direct action of the parasite are always but a small practical part of the same. The mere destruction of the animal in all its phases may be, therefore, only a part of treatment, although always the first and essential step. It is important therefore, first, that in the choice or combination of remedies those should be selected which shall destroy the animal with certainty and quickness, and yet shall not aggravate the existing inflammatory changes in the skin; and second, that they should not be used too long.

Dr. White says he generally employs in dispensary practice the following method, and that it is applicable in every case, however extensive or severe may be the accompanying inflammatory processes. He prefers a mixture of the three active agents (a scattering shot), and combines them in this way.

℞ Flowers of sulphur . . . . . ℥ ii
β-naphthol . . . . . ℥ i
Balsam of Peru,
Vaseline . . . . . āā ℥ i
M.

This quantity, he says, is generally sufficient for the cure of a single case. The patient is directed to rub a third of this mixture into the whole surface of the body, from the neck downward, at bedtime. He is especially told to rub it between the fingers and upon the penis, and that it must be applied to the back by some other person. He is to sleep in old garments, that the bedclothes may not be soiled. In the morning the skin is to be thoroughly washed with soap and water. The use of the bath in this class of patients is of course out of the question, nor is it essential. The ointment is to be used in this way for three consecutive nights. Generally the itching ceases almost wholly on the first application. The patient is also told not to use it after the third night, unless, after waiting two more nights, there should be a decided return of the pruritus here or there, in which case the salve is to be rubbed into such parts only, and only for two nights running. For very young children he omits the naphthol in prescribing the ointment, on account of its occasional irritating properties.

In cases in which the accompanying eczema is severe, it is well to require an inspection of the patient again on the sixth or seventh day, when it will sometimes be found necessary to direct a course of treatment addressed to this residuary condition. He warns the physician that a very frequent mistake at this stage is the conclusion that the appearances, or accompanying itching, are signs of the continued activity of the original affection, and the consequent renewal of the use of the stimulating parasiticide, which only aggravates the existing process. He has often seen cases of post-scabietic eczema in dispensary and private practice, which have been kept going for months by such errors of judgment. It must also be remembered that in prolonged

cases of itch the cutaneous nerves have acquired, as it were, the habit of demanding to be scratched, and seem to require it for a long time after every visible sign of the disease has disappeared, and these cases of surviving pruritus are often mistaken for remaining evidence of the original affection, and mistreated accordingly.

Directions are always given that on the first night of the treatment all the clothes which have been worn next to the skin,—shirts, drawers, and socks, and the sheets and pillowcases last slept in,—shall be thoroughly boiled before being used again. Gloves should be baked or destroyed. It is to be assumed that every bed-fellow has the disease also, and requires treatment as much as the patient. Every member of the family should, he says, also be inspected and treated in the same way, however slight in character or extent may be the indications of the affection. He says he has seen the disease keep up a continued and alternating existence in a large family for a year, during which period nearly all its members underwent treatment one or more times, simply because they were not treated simultaneously. He has recently directed five members of a private family to be thus generally treated, although only two of the household at that time presented any positive indications of the presence of the disease.

As to the more general control of the affection in its well-nigh epidemic state of prevalence, it is only by drawing the attention of the profession to this activity, and to the best methods of destroying it in individual instances, that it may be hoped to accomplish anything.

The Microbe of Diphtheria.

The announcement of the discovery of the microbe of diphtheria by MM. Roux and Yersin of the Pasteur Laboratory, has led somewhat prematurely to sanguine hopes that the disease will now be amenable to prophylaxis by inoculation. The micro-organism of diphtheria, however, has been before now discovered by such investigators as Oertel, Klebs, and Loeffler. Nevertheless, but little fruit in the direction of successfully combating this highly fatal disease has yet accrued from these researches. We await with interest the full details of this latest inquiry, and shall be glad to see to what extent MM. Roux and Yersin have advanced beyond the stages reached by their predecessors in this field.—*Lancet*, Feb. 9, 1889.

Parasites and Monkeys.

At the last meeting of the Academy of Natural Sciences, of Philadelphia, Mr. Ives stated that, while examining a specimen of a monkey, the sooty Mangabey, which recently died in the Zoological Garden, he had found in the omentum and distributed through the lungs, peritoneal cavity and elsewhere a curious parasite, allied to the mites and ticks. It had also been found in the mandril, the Macaque and the Chacma baboon. The animals present curious modifications, fitting them for their parasitic existence. The monkeys in which these parasites occur are all old world species, and it becomes an interesting question whether they were developed in the Zoological Garden or before the capture of the infested animal.

In answer to an inquiry the President stated that there is no marked correspondence between the parasites of man and those of the higher apes. As far as he is informed the same species of tape worm does not occur in man and monkeys, although Trichocephalus dispar and the round worm Ascaris lumbricoides have been found in both.

New Amber Beds Near Dantzig.

The district of Heubode, near Dantzig, has suddenly become the scene of considerable speculation and of a good deal of activity in consequence of recent discoveries of amber made there. The main region of the shores of the Baltic, where amber has hitherto been found in paying quantities, is between Pillau and Grosz Hubenicken, some distance to the east of the present find. The attention of the authorities was first called to the matter some years ago by a person who offered 1,800 gulden (about $720) annually for the exclusive privilege of mining amber in the district. For some reason it was not accepted, and the matter was dropped until very recently, when the offer was renewed, the sum being increased to 6,000 gulden. It was accepted, and the parties have gone to work on a three years' lease at these figures. After the lease was executed the authorities received an offer, from another person, of 1,000 gulden monthly for a period of six years, or a cash in hand price of 72,000 gulden for the same privilege. These figures indicate that somebody is confident of finding amber in large quantities in the new field.—*National Druggist*, March 1, 1889.

The Bacillus of Diphtheria.

Dr. George M. Sternberg, in a lecture delivered at the Hoagland Laboratory, Brooklyn, Jan. 26, reviews the investigations made by different bacteriologists to determine whether or not there is a specific bacillus of diphtheria. In conclusion, he says that the experimental evidence, with reference to the etiological *rôle* of Loeffler's diphtheria bacillus is rather more satisfactory than that which has been adduced in favor of the relation of Eberth's bacillus to typhoid fever, or Koch's "comma-bacillus" to cholera; and that most conservative bacteriologists seem inclined to the view that it is in fact the specific infectious agent in this disease.—*Brooklyn Med. Journal*, March, 1889.

Cocaine in Angina Pectoris.

Professor Valerian G. Lashkevitch, of Kharkov, tried (*Novosti Terapii*, Dec. 1888, p. 440) hydrochlorate of cocaine internally, in the dose of one-third of a grain, three or four times a day, in sixteen cases of angina pectoris associated with cardiac or vascular disease, or, as in some of the patients, angina apparently caused by excessive tobacco smoking. The results obtained justify the author in regarding cocaine as a genuine specific remedy for the affection. The attacks of angina were invariably relieved even on the second day of the treatment, and ceased altogether and permanently in the course of a few days. Recovery takes place still more rapidly, when inhalations of oxygen gas are simultaneously employed.

A Fatal Prescription.

The recent death in Germany of a child as the result of taking a prescription containing an incompatible and dangerous compound, viz., chlorate of potash and iodide of iron, deserves the attention of all practitioners. The iron was precipitated in the form of the sesquioxide, and all the iodine liberated. The following formula will illustrate the chemical changes which took place in the medicine: $2FeI_2+KClO_3=Fe_2O_3+KCl+4I$.

Creasote with Cod-liver Oil and Saccharin.

Dr. Seitz gives the following formula in the *Therap. Monatshefte*, 1889, No. 48:

Creasote	2.5 parts
Cod-liver oil	200 "
Saccharin . . .	1 "

Dose: A tea to tablespoonful, 1 to 3 times daily for adults; for children the amount of creasote should be less.

Bill for Adulteration of Food Defeated.

The House Judiciary General Committee of the Pennsylvania Legislature decided on March 8, to report negatively the bill advocated by the Society to Prevent Food Adulteration. The bill was aimed to prohibit harmful and deceptive and regulate harmless and necessary adulteration of food and drugs. Ex-President Kline, of the Philadelphia Drug Exchange and of the National Wholesale Druggists' Association, and Dr. Robbins, President of the Pharmaceutical Board, were before the committee in opposition to the bill so far as it related to drugs. They said it would cause heavy and unnecessary expense, and admit inspectors to rooms where they could learn valuable business secrets. Besides, they thought there was already enough law on the subject to protect the people, although it might be well to increase the penalties for violation. President Ammerling, of the Anti-Adulteration Society, vainly tried to convince the committee that the bill ought to be passed.

Athletic Sports and Gymnastics at the University of Pennsylvania.

It is stated that the opinion has prevailed among the medical students of the University of Pennsylvania that it is impossible for them to devote any time to athletic exercise without lowering their class standing and failing in their examinations. But a number of medical students who are in training for the crews have formed an "Oarsman's Quiz Club," and every day, after they have taken their pull, they meet and quiz each other on the subjects which they must prepare upon for examination.

There has been some difficulty experienced in having the department of physical education established on an equal basis with the other branches as regards compulsory attendance and ranking in class. When the department was first introduced at the University it was said that hours would be assigned for gymnasium work just as for recitations or lectures. An attempt was made to introduce this feature into the regular curriculum, but it never succeeded for lack of interest and support in different quarters. Dr. Leuf, the Director of Physical Education, has now succeeded in having regular gymnasium hours assigned to the two lower classes, and it is said that the Trustees are endeavoring to secure a permanent instructor, so that the gymnasium may be open regularly for several hours every day.

NEWS.

—The Trustees of the University of Pennsylvania have just purchased from the city three properties, amounting in area to nine and a quarter acres, in the vicinity of the University, paying $149,800.

—Dr. S. Weir Mitchell, of Philadelphia, has written a story of life in the lumber regions, which the Lippincotts will publish. Its title is *Far in the Forest.* The work is said to be an outcome of personal observations among an interesting class of people.

—The Philadelphia *Ledger,* Feb. 23, 1889, reports that a young woman died in a dentist's chair in Norwalk, Ohio, on Feb. 21. She had taken chloroform preparatory to having teeth drawn, and it caused her heart to cease beating. It is thought she was affected with heart disease.

—The Woman's Medical College of Pennsylvania held its thirty-seventh annual commencement March 14, and conferred the degree of Doctor of Medicine upon 36 graduates. Dr. Clara Marshall, Dean of the College, presided, and the address to the graduates was delivered by Dr. James B. Walker.

—At the meeting of the College of Physicians of Philadelphia, March 6, a report of a committee, setting forth the importance of "a rigid inspection of meat and milk," was adopted and a committee was appointed to act with other bodies with the view of obtaining legislation to accomplish the desired ends.

—The *British Med. Journal,* Feb. 9, publishes the conclusions arrived at by the physicians who made the autopsy on the late Crown Prince Rudolph, of Austria. There seems to be no doubt that he shot himself, and the conditions of his brain and skull justify the supposition that he was mentally deranged.

—Dr. Alvan Talcott, of Guilford, Conn., who has given $25,000 to endow a professorship of Greek at Yale, is one of the oldest alumni of that university, having been graduated in 1828. He is past eighty years old, still practises medicine, and reads Homer daily with far more earnestness than ever in his undergraduate days.

—On March 4, Dr. A. L. Loomis was examined in New York City in the suit brought against him by the widow of the late Dr. Miller, which was referred to in the REPORTER March 9. The manuscript of the essay said to have been written by Dr. Miller was in Dr. Loomis's handwriting, and Dr. Loomis testified that Dr. Miller's work on the essay had consisted in engrossing some tables and copying them afterward for publication; he did not revise or do any original work upon the essay.

OBITUARY.

AUGUSTUS F. TAYLOR, M.D.

Dr. Augustus F. Taylor, an ex-Mayor of New Brunswick, N. J., and one of its oldest residents, died March 6, at the age of eighty years. He was educated at Rutgers College, and was one of the oldest graduates of that institution. He studied medicine and began its practice nearly sixty years ago. He sailed for California in 1849, and amassed a fortune. On his return he resumed the practice of his profession, and continued it until eighteen years ago, when he lost his eyesight.

PHILIP D. MARSHALL, M.D.

Dr. Philip D. Marshall, of Reading, Pa., died March 5, of pneumonia, at the age of fifty-six years. He was a graduate of Jefferson Medical College, Philadelphia, and was a surgeon for a number of years in the United States Army, having been stationed for a long time at Jefferson Barracks, near St. Louis, Mo. He was an intimate friend of Dr. Joseph Pancoast, and was the first surgeon to perform the operation of tracheotomy in Reading. He was prominent in his profession, and was the author of many valuable papers on surgery.

CHARLES E. L. WAGNER, M.D.

Dr. Charles E. L. Wagner died in Hanover, Germany, Thursday, March 7, 1889. Dr. Wagner was born in Hanover in 1823, was graduated at the University of Göttingen in 1847, and entered the Hanoverian army in the same year. During the Schleswig-Holstein war, of 1848–1849, he served as surgeon in the army, and in 1855 he entered the British army as surgeon of the Third Regiment — British German Legion—serving during the Crimean war.

In 1860 Dr. Wagner came to the United States and took up his residence in Wilkes-Barre, Pennsylvania, where he remained, practising medicine, until 1874, when he retired from active practice and spent most of his time abroad, returning however to this country every few years. He had already engaged passage for his return from Germany to this country when he was stricken with apoplexy and called away suddenly to a better and everlasting home.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA

Among many points in which this preparation excels, are:

1st.—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d.—In the **Proportion of Oil** it contains.

3d.—In mode of manipulation and thorough incorporation rendering it **Permanent** and **Palatable,** and of proper consistence, **About that of Rich Cream.**

4th.—**In Size of Bottles** containing nearly 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

The new Hospital building situated in the centre of the city, has accommodation for twenty patients and ten private rooms. Each private room has a special nurse, electric-bells, open fire-place, and meals privately served. Pay patients may enter the Hospital at any time previous to their confinement. The hygienic arrangements and sewage of the Hospital are perfect. Ample protection is provided against fire. A limited number of free and pay beds are reserved in an isolated portion of the building for Gynaecological cases.

Two courses of instruction in practical obstetrics and in practical gynaecology are given each year commencing in April and in October. Free patients only are used for purposes of clinical demonstration.

For particulars as to the admission of patients, or the courses of instruction in obstetrics and gynaecology, apply to DR. CHARLES MEIGS WILSON, Physician in Charge, by letter or in person, at the Charity, S. W. Cor. 11th and Cherry Sts. Phila., daily at 12 o'clock noon.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

CÆSAREAN SECTION FOR CARCINOMA OF THE CERVIX UTERI: THE NEW SÄNGER OPERATION.

BY WILLIAM GOODELL, M.D.,
PHILADELPHIA.
PROFESSOR OF GYNECOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

This woman, 32 years of age, was married before she was 15. She has had eight children at term and four miscarriages. A year ago last February she began to lose blood per vaginam. This was neglected until some time later when an examination revealed the existence of cancer of the cervix. In October last this was curetted and the hemorrhage ceased. At that time the fact that the woman was pregnant escaped notice. About two weeks later, however, the fœtal movements apprised the mother of her condition. This is a very scant history, but it is all that we are possessed of. By a rough reckoning, I conclude that the pregnancy is now within about ten days of its normal duration. Now, why am I going to operate on this woman? I shall do so because the whole vagina is blocked by a dense, scirrhous mass that is impassable. In its present condition it would be impossible for the cervix to dilate sufficiently to permit of the passage or extraction of the child. If we allowed the case to proceed to labor, it would probably prove fatal both to the mother and to the child. I think it wisest to operate now while the woman's morale is good and her strength is fair, because the hemorrhages have returned, and because we can select the time of the operation. The sole objection, and not a very important one, to this immediate operation is the absence as yet of canalization of the cervix. The period of election for the Cæsarean section is after the beginning of labor when the cervical canal has dilated sufficiently to permit of the escape of the waters and of the subsequent drainage of the lochia. On the other hand, such an

amount of dilatation in this case would probably require many hours of exhausting labor for its production, and I shall, therefore, produce it artificially. We have here, according to my diagnosis, a breech presentation. The body of the child is lying in the left half of the uterine cavity, and yet, which is somewhat singular, we hear the sounds of the fœtal heart much more distinctly over the right side of the mother's abdomen. As to the statistics of this operation, the old Cæsarean section was very fatal. It was generally undertaken too late, after the forceps had been tried for a long time, and when the woman was almost or quite in extremis. Sänger, of Leipsic, has recently devised an improved method of operating, the results obtained by which have been much more satisfactory. Our great statistician, Dr. R. P. Harris, who has honored us by his presence to-day, tells me that thus far there have been in the whole civilized world 163 operations by the Sänger method, with 45 deaths—viz., a mortality of 27⅝ per cent. In this country the showing is not so good, there having been 26 operations with 16 deaths. This larger mortality is probably due to the fact that the woman was not operated upon until every other means had been tried, and she had become exhausted by the delay, and injured by the efforts made to deliver her per vaginam.

There is one thing to be said concerning my patient. She has displayed a wonderful amount of nerve and pluck, and, while she appreciates the danger to which she will be exposed, she yet feels much confidence in the result. One reason for this is, I think, that since she has been here she has seen many women recover from operations which have been performed for the removal of tumors, etc. Since the beginning of this session my son and I have performed twenty-three such operations in your presence, and with but three deaths. Only one of these was from septicæmia, the patient's death being almost a foregone conclusion. The tubes and ovaries were distended with rotten pus, and were everywhere so adherent that they burst and deluged the belly with putrid matter; nor could the ovaries be wholly removed. The second death was due to shock, after the removal of a large uterine sarcoma by supra-vaginal hysterectomy. The patient was very feeble and had been bed-ridden for many months. The third death took place in the fourth week after the removal of pus tubes and ovaries, and was in no wise due to the operation. The patient had paralysis of the lower extremities and displayed a mental hebetude which I deemed hysterical. But my diagnosis was evidently incorrect, for her subsequent history plainly showed some obscure but serious cerebro-spinal lesion. For over a week after the operation she did extremely well, then symptoms of general paresis developed themselves, the sphincters gradually lost power, and death finally resulted from the advance of the cerebro-spinal disease.

Our patient lying before us has shown wonderful pluck. With the prospect of death before her, she has displayed no fear, but she has made a last request of me which I have promised to fulfill. It is that her child be baptized as soon as it shall have been delivered.

And now, with the statement that all the external parts involved have been antiseptically cleansed, and the vagina disinfected by a bichloride of mercury solution, I shall begin the operation. Having opened the abdominal cavity and exposed the pregnant uterus, I may proceed in one of two ways. I may either lift the womb and bring it out through the opening that I have made in the abdominal wall, and then incise it and extract the child, or, I may open the womb *in situ*. By this latter method some of the fluid contents may enter the abdominal cavity, but the abdominal incision will be much shorter. (The uterus was now opened, *in situ*, and the child delivered; shortly afterward the placenta was detached and removed with the membranes.) I now bring the emptied womb out on the abdomen, and control the hemorrhage by an elastic tube thrown around its lower zone. You will notice that the womb was raised up and the abdominal cavity was packed with sponges to catch any fluids that may have escaped from the womb. I shall first introduce the deep sutures into the walls of the uterus. These are inserted in this way. The needle enters the uterine wall a half inch from the edge of the womb and is carried obliquely downward and inward till it emerges just above the edge of the mucous lining of the womb. It is not allowed to penetrate this inner membrane for the reason, that a communicating channel might be established along the course traversed by the suture, and through this some of the fœtid and septic contents of the uterus might escape into the peritoneal cavity. After all the deep sutures have been inserted, the closure of the wound is completed by the insertion of a number of Lembert sutures. By these latter

stitches we secure the turning in of the cut edges of the serous investing membrane of the uterus and their maintenance in close contact. Why does the present technique (Sänger's) yield better result than the old operation? It is, I think, because of the great care that is now exercised in the closure of the uterine wound. It is upon the careful introduction of the deep and the superficial Lembert sutures and the adoption of rigid antiseptic precautions, that the increased success of the operation seems to depend. You may ask why I did not perform the "Porro" operation here. For two reasons. First, it is slightly more fatal than the Sänger operation; and, secondly, I found that it would be impossible to remove the womb in its entirety. If I could have succeeded in removing the whole womb, I should have done the "Porro," but I found the walls of the bladder and rectum so infected by the disease, so hardened and massed together, that complete hysterectomy was quite out of the question. You saw that the child presented by the breech, thus verifying my diagnosis. The woman has had two such presentations before. She has been a very prolific mother, one of her four miscarriages having been with twins.

We have now completed the closure of the uterine incision, and, on counting our stitches, we find that we have put in fourteen deep and seventeen superficial or Lembert sutures. These, with the natural contraction of the womb, effectually control any hemorrhage. The parts are now thoroughly well cleaned, the womb is sponged off, and the space between it and the bladder carefully examined and cleaned. Although this has been a very clean operation, I shall take the additional precaution of thoroughly irrigating the peritoneal cavity previous to closing it. We shall use ordinary water that has been boiled. The cutaneous sutures will be first introduced and the irrigation then performed before they are drawn tight. In placing these sutures we should endeavor to secure such a union of the divided abdominal wall as shall prevent the occurrence of a subsequent ventral hernia. We want to bring forward as much tissue as possible. It is particularly necessary to draw the rectus and its tendon well into the line of union and get them in accurate apposition, and if there should be any difficulty in doing this we may resort to traction on the tendon by a pair of forceps. In spite of our best care, however, these hernias will sometimes occur, and I should like very much to know of some method by which they can be wholly avoided. I am going to cut her navel out. It is a dense mass presenting a very hard and narrow surface, which is liable to give way and cause hernia, so I shall excise it. The anæsthetic that has been used during this operation is chloroform. Whenever pressure is exerted either upon the respiratory organs or the kidneys by the presence of a tumor, and we can certainly call the pregnant uterus by that name, I prefer the administration of chloroform to that of ether. I use it altogether in my private laparotomies. When the renal vessels are subjected to any pressure and ether is used as an anæsthetic, the kidneys may suddenly become congested and stop work, with resulting uræmia and death. Ether is also strongly contraindicated where albumin is present in the urine, and in the aged who have bronchial affections.

Now that all our abdominal sutures have been introduced, we shall irrigate this abdominal cavity. Again, I say, we shall use only plain boiled water. This manner of paddling about with my hand among the loops of intestine may look like rough work, but it does no harm. I now draw the omentum down over the intestines and the womb and proceed to close the cavity. (The abdominal sutures were drawn tight, tied, and the redundant ends cut off. All soiled linen, towels, etc., were then removed from the woman and she was sponged perfectly clean. The wound was freely dusted with iodoform, a layer of iodoform gauze (50 per cent.) laid over it, on this a layer of carbolated gauze, and then a broad, thick mass of baked cotton, which was firmly held in place by strips of adhesive plaster. Over all a flannel binder was applied.)

Now that we have completed the operation and the dressing, the last thing that I shall do will be to pass my finger within the vagina and clear a channel through the cervix that shall permit the escape of the lochia. I might have done this from above before I closed the uterus, but I was afraid of contaminating my fingers with the cancerous juices, and so I postponed it till now. I wish to avoid as far as possible the use of opium in the subsequent treatment of this case. If much pain should be complained of, of course, we cannot withhold it altogether. The woman will now be removed to her bed, she is in good condition, and I think she ought to recover. In looking back over the operation I do not think we have omitted anything that might have added to the patient's chances of recovery.

I may, possibly, have made one mistake in delivering the child by the head instead of the feet, thus necessitating a somewhat larger opening in the womb, but the child presented with the breech, which placed the feet at a distance from the incision, and it was easier to deliver by the head. Nor do I think that this will militate in any perceptible degree against a favorable result.

[Twelve days have now (March 25) elapsed since the operation, and the patient is apparently out of danger. She is eating and sleeping well, and she has an abundant supply of milk for her infant, which is thriving.]

COMMUNICATIONS.

THE INFLUENCE OF STOMACH DIGESTION ON THE HEART'S ACTION, AS A PROXIMATE CAUSE OF HEART FAILURE.

BY WILLIAM H. BURR, M.D.,
WILMINGTON, DEL.

On the night of Nov. 18, 1888, I was called up at 12 P.M. to visit a man who was said to be very ill. I reached the patient's house in about fifteen minutes, and found that he had been dead ten minutes. I found him on his knees, with his head bent over on the pillow where he had dropped it in the act of vomiting. His face and neck were deeply congested. When the patient's head was lowered a small quantity of bloody fluid oozed from his mouth.

History of Attack.—At about 11.30 P.M., shortly after retiring, the patient complained of fulness of the chest, was deathly pale, and began to rift and belch up quantities of gas, which somewhat relieved him for a time. The fulness and oppression increased, and with them there was agonizing pain over the whole region of the chest, especially over the left side, and extending to the bowels. His wife went into another room to procure some remedy and on returning found the patient on the vessel purging. He got into bed again, but immediately rose to vomit, bringing up with great effort and straining a small quantity of partially digested food, accompanied with a little dark, bloody fluid. He now complained of being intensely cold—"freezing to death," as he expressed it. His extremities were cold and clammy. He attempted to vomit every few minutes, leaning over the foot of the bed and pressing on his chest and stomach, each attack being accompanied with agonizing pain. He then sat up in bed and begged the assistants to bathe his limbs in hot water as they were freezing to death. He put his hand over the region of his heart, and wondered if it was his heart that was troubling him. Suddenly he got up on his knees for the last time, in an uncontrollable attack of vomiting, his wife supporting him, and while in the act, he fell forward with his head almost in the basin, gave one or two gasps, and was dead.

Post-Mortem.—The lungs were apparently healthy, but much congested, containing blood of arterial hue. The heart presented marked signs of fatty degeneration; the left ventricle was hypertrophied, the right dilated, thin, and tearing easily; the valves were healthy, with no atheromatous change. Liver much enlarged. Bowels, congested. The stomach was well filled with partially digested food. The kidneys were apparently healthy, except that the left had an adherent capsule and showed signs of old inflammation. All the internal organs except the lungs were filled with an immense quantity of uncoagulated blood, black, and tarry-looking. All the blood in the body seemed concentrated in the internal organs.

Previous History.—The patient had for several years been troubled with occasional attacks of indigestion, at which times he would eructate quantities of bitter fluid, have a bitter taste in his mouth, all of which would disappear under appropriate treatment. He had been treated eight or ten years before for enlarged, torpid and painful liver.

Twenty-five years ago he had an attack of acute nephritis, which confined him to his bed for six weeks and from which he suffered for three years afterward, apparently recovering, with the exception of occasional attacks of congestion of the kidneys since. Three years ago we removed a large sarcoma of the left testicle, which disease had developed in an undescended and undeveloped testis and was of ten or fifteen years' growth. It had showed a decided malignant tendency for the last six months before we operated. There was never any indication of return. The patient's wife reported that, though he had never consulted a physician for the trouble, he had had occasional dyspeptic attacks, as he called them, the first one of which we have a record being twenty years ago, the last one being the attack which resulted in his death, previous to which he had not had any

for a long time. The symptoms at each attack were exactly similar, though not so intense as during the fatal attack. He would have fulness, oppression, and pain, only relieved by retching and rifting, with never any vomiting, but with congestion of the veins, and sometimes distension of the bowels with gas, and œdema of the tissues over the abdomen.

The patient had always been a hard-working man, lifting and straining in his work from 5 A.M. to 11 P.M. He was a slight man, weighing about 130 pounds, and had the facial appearance which is described as being found in cases of fatty heart, *i. e.*, the veins of the neck being habitually distended, and the countenance looking dusky and anxious.

In a second case of this sort which came under my observation, a large portly, full-fed man, noted for mental acuteness and application, on a warm summer day, after eating a full meal, started to walk to his place of business. About half the distance had been traversed when he became deathly sick, complained of great pain through the chest, had an attack of vomiting, and died in a few minutes.

Post-Mortem.—Every organ in the body was perfectly sound and without disease. The stomach contained almost all of the large dinner he had taken. No evident attempt at digestion had taken place.

In a third case a young man, in the evening, shortly after eating, was taken with vomiting. Upon the arrival of medical aid he was almost pulseless, his heart was acting tumultuously and irregularly, his surface was cold and clammy, his respirations diminishing. A prompt emetic of mustard and water was administered, and the patient vomited immense quantities of hard lumps of curdled albumen, some of them as large almost as an adult fist, so large that it seemed incredible that they could have passed through the gullet.

With the vomiting the symptoms improved, and from a condition of collapse bordering on death the patient became convalescent. A slight amount of low grade of pneumonic inflammation developed, but it was successfully treated and the patient recovered.

These cases are not entirely similar. The last two belong more especially to that class of cases denominated paralysis of the stomach. But they all show very decidedly the effect of suspended or difficult digestion on the action of the heart and lungs. They show, what is seldom adverted to in the books, that a nerve storm may develop in the stomach and bowels which shall overwhelm and bring disaster on the circulatory apparatus and lungs, and cause death. There also seems to be a lesson to be drawn here directly from nature, for does she not in these cases undertake to rid the system by purging and vomiting of those matters which are causing its death? And if, by assisting nature to throw off the *materies peccans*, we can tide the patient over such a danger it is adding much to our therapeutic resources. Hlasko has investigated the question of the cranial center for the stomach movements with results which lead him to conclude that the center for the constrictor fibres of the cardia lies in the corpora quadrigemina, and that it is connected with the stomach chiefly through the vagus, but partly by the spinal cord and sympathetic system. The center for the dilator fibres, and for those that control the movements of the stomach walls also, are supposed to lie in close proximity. Another author believes that the center for vomiting lies in the corpora quadrigemina.

The *par vagum* is composed of both motor and sensory filaments, and, besides other organs, supplies the stomach and heart with motor influence. The stomach and heart, as every one knows, are intimately connected through the cranial and sympathetic systems. Would it be strange then if that much abused organ of digestion, the stomach, were to refuse to act, it should inculpate with itself the organs most important to life with which it is so intimately connected, which organs stop not day or night and know no rest except it be the rest of death? That this is due to nervous sympathy and not to mechanical pressure is clearly demonstrated, as the heart can be bent into almost any position by effusions, and be more or less cramped, without complaining seriously of such distortion.

Vomiting itself in a healthy person will often induce faintness and almost a state of collapse. When the heart is already crippled it falls an easy prey to even a slight sympathetic disturbance.

There are several questions which might be considered in regard to the treatment of these cases. Almost nothing is written in the various text books in regard to the symptoms portrayed above and their proper treatment; so that when the practitioner is brought for the first time face to face with such a case, hovering on the brink of the grave, he is without advice and without weapons. There are but a few moments to do anything. Something must be done, and

that quickly. The balance, which for years has been ready to go up or down at a moment's notice, has turned the wrong way.

What shall we do? Are there no means to whip the tired organs into renewed activity, to tide the patient over the terrible crisis until we may bring such slower agents to bear as change of occupation and general attention to building up the health?

The first case was undoubtedly one of cardiac failure, due to fatty heart, which was itself largely caused by the anæmic conditions and mode of life of the patient. The circulation was so weakened that the act of vomiting itself was almost enough to cause collapse. The treatment here, based upon the symptoms taken with the result of the *post-mortem* examination, would seem to have been to stop the vomiting immediately, to strengthen the weakening circulation with morphia and atropia administered hypodermically in *hot* solution, and the administration of hot whiskey and ether hypodermically, with the use of hot bottles and hot bathing.

In the second case there was no history of heart disease previously, and here death was obviously caused by the paralyzant action of the large masses of food which the stomach, unable to digest easily, had refused to act on at all. Here it would seem that the first object should be to empty the stomach and at the same time, or afterward, to stimulate the flagging circulation. In the third case, the same line of action would seem to be indicated, and was adopted with the result of saving the patient's life.

To conclude, it might be asked: are the vomiting, retching, pain and discharge of fermented gasses in fatty heart due to passive congestion of the stomach and bowels, which congestion is the first act in the tragedy of failing circulation?

Again, does that congestion occur unavoidably, or is the presence of undigested or difficultly digested food the cause of the trouble, producing first congestion of the internal organs, then the pains and irritative symptoms, crippling of circulation and death? Lastly, in the paralyzant cases there seems to be no doubt but that death is caused by direct nervous paralysis, sympathetic in its nature.

—A number of the crew of the bark Fannie Skalfield, which arrived at Jersey City from Calcutta March 13, were affected with scurvy. One of the crew died and two were reported to be likely to die.

CROWDED HOSPITALS FOR THE INSANE.

BY JOHN CURWEN, M.D.,
SUPERINTENDENT OF THE STATE HOSPITAL FOR THE INSANE, WARREN, PA.

The consideration of the overcrowded condition of the different State Hospitals for the Insane of Pennsylvania has been a matter of serious concern to the trustees and officers of the institutions, and on the part of some of the hospitals action has been taken which follows too closely the English plan to be acceptable to the majority of the people Without entering into a full statement of the manner in which the crowded state has been brought about, it is sufficient to say that an effort has been made by the Committee on Lunacy to remove all the insane from the almshouses, while there was not room in the State Hospitals for their accommodation without unduly and improperly crowding them, and rendering all uncomfortable and more liable to disease from the effects of such overcrowding.

Among those thus removed to the hospitals were a large number of imbeciles and very many quiet and demented insane, for whom only simple custodial care was needed. The law is express in its requirements that recent cases shall have preference over those of long standing. Every one familiar with hospitals for the insane knows that for recent cases quiet and freedom from unpleasant surroundings are essential to the obtaining of that rest and sleep which are a first requisite in treatment. How can this be properly secured when the rooms are all occupied, and to give proper accommodation some one must be crowded out into closer quarters to give even a measure of the accommodation demanded?

Crowding, and worse, overcrowding is a serious bar to all proper classification, and without proper classification, so as to separate the quiet from the excited, the restless and fretful from others over whom they may exert an improper influence, the requisite treatment cannot be fully and advantageously carried out. In confirmation of this statement the following resolution of the Association of Medical Superintendents of American Institutions for the Insane may be quoted: "That this Association regards the custom of admitting a greater number of patients than the buildings can properly accommodate, which is now becoming so common in hospitals for the insane, in nearly every section of the country, as an evil of

great magnitude, productive of extraordinary dangers, subversive of the good order, perfect discipline and greatest usefulness of these institutions and of the best interests of the insane."

It is not with recent curable cases that the hospitals are crowded, but with those classes which have been gradually accumulating in the almshouses, or have been kept in private families until the families have found it impossible longer to bear the strain.

In the State of New York twenty years ago it was thought that the establishment of the Willard Asylum for the chronic insane would in a large measure relieve the other hospital and also remove the insane from the county poorhouses. That institution has now in its charge about two thousand patients, but in the years since its establishment the hospitals at Buffalo, Poughkeepsie and Middletown have been built, and they are now crowded; the Inebriate Asylum at Binghamton has been converted into an asylum for the chronic insane, and it is full, and another asylum to accommodate a large number of insane is in course of erection near Ogdensburg; while nineteen counties in the State have been authorized to construct buildings for the insane in connection with the poorhouses. In the above enumeration no account has been taken of the insane of the city of New York and in the adjoining counties on Long Island, for whom provisions have been made in those localities.

In Pennsylvania the hospitals for the insane are all overcrowded, and the majority of the poorhouses which have accommodations for the insane are nearly empty. In many counties of this commonwealth there are very good accommodations for the insane, arranged specially for them; but notwithstanding this fact all the insane have been removed to the State Hospitals, overcrowding them, and impairing their usefulness and efficiency of treatment, without any corresponding benefit to those removed, but on the contrary rather placing them where they cannot have the amount of space they should have and adding to the discomfort and annoyance of those in the hospital before their admission. The taxpayers certainly have some rights to be respected in such cases, and in the counties in which large sums of money have been expended in the erection of accommodations for their quiet and demented cases, there is a general feeling of discontent that the accommodations erected at such cost should be practically useless.

Just here the plain practical question meets us: Shall we impair the ability and efficiency of the hospitals for the insane to take just and proper care of the recent cases so that they may be restored and returned to the community as producers and taxpayers to aid in relieving the burdens of the community? or shall we crowd the present hospitals with imbeciles and quiet demented patients who can be well taken care of in the almshouses, under proper regulations?

The Board of Public Charities has, in each county where there is an almshouse, a committee of visitors whose duty it is to visit the almshouses and jails regularly; then there is the General Agent of the Board and the Secretary of the Committee on Lunacy. With these means at command a careful and systematic visitation of the different almshouses can be made, and the manner in which they are kept and the inmates are attended to can be strictly observed, and all abuses can be prevented or corrected.

With such a system in full and regular operation the objection that the insane and imbeciles would not be properly taken care of would be obviated, and by careful selection of those to be removed from the hospitals, the overcrowded condition of the hospitals could be relieved and better accommodation given to the recent cases, to those who must be kept in the hospital on account of their excitable character, and to those from districts where no accommodations of any kind are now provided.

The theory that the State should provide for all the insane is correct and true, but in actual practice such a condition has not yet been realized; and, however much it may be desired, it is not probable for financia reasons that it can be realized for some years to come, and while laboring and waiting for such a desirable end, we must use the best means at command for the relief of those who are now to be cared for.

That such quiet, chronic cases can be made as comfortable in a hospital where they are compelled to sleep from fifty to one hundred in one room, as in an almshouse where each can have a room or where only three or four are placed in one room, the writer of this does not believe; nor does it seem in the nature of things reasonable and right. The present effort seems to be to treat the insane in masses and not as individuals, and that is a sure way to add to the already large number of chronic cases.

The more thoroughly individualized the treatment the greater the prospect of success in that treatment, and of restoration to sound mental health.

Society Reports.

PHILADELPHIA OBSTETRICAL SOCIETY.

Thursday, February 7, 1889.

The President, Theophilus Parvin, M.D., in the Chair.

Dr. Horatio R. Bigelow through the Secretary read a paper on

Apostoli's Placé in Gynecology.

After some complimentary remarks on Apostoli himself Dr. Bigelow went on to discuss the armamentarium necessary for carrying out the electrical treatment. He thought it necessary to have a galvanic battery, a Faradic battery, a collector, a galvanometer, intra-uterine electrodes for both currents—and one for carrying both the positive and negative of the induced current within the uterus—bulbous, charcoal-pointed electrodes of various sizes for galvano-caustic applications, intra-uterine platinum electrodes, and large bulbous vaginal and rectal electrodes. The belly-plate could be made of potter's clay, in which the metal plate could be buried; or better still is the plate devised by Martin, of Chicago. A good galvanic battery should have a slight chemical action and great constancy. The Leclanché cells or those of Daniell he thought the best. With 36 Leclanché cells, without a rheostat, a strength of from 300 to 350 milliamperes can be had. He thought the collector invaluable, and that to measure the dosage exactly is an absolute pre-requisite of success The best galvanometer is that made by Gaiffe. The best Faradic battery is that of Gaiffe with a chloride of silver-pile, and the induced current of high tension from the long thin wire the one to be generally used, within the uterus.

"The induced current penetrates the tissue profoundly by reason of its high tension, but contrary to physical laws, the continuous current of low tension, has a longer and more profound action. We have proved the diffusion of the electric currents and that the galvanic current propels itself through organic tissues, its influence being felt at remote points; the current *never remains limited between the two poles.*" (Onimus.) "If we now consider the difference that exists between continuous and induced currents during their constant passage we find that it is not difficult to distinguish between them, as the line of demarcation is clear. The induced current acts for an exceedingly short time during its passage. It produces at each instant of passage a greater or less excitation and causes molecular shock. The induced current acts mechanically as an excitant, but the continuous current penetrates more gradually the tissues but more profoundly, acting chemically in such a way as to produce molecular orientation and chemical combination" (Onimus).

The induced current traversing the liquid, semi-liquid, or solid substances that go to form the human body, produces no chemical action whatever, simply a mechanical molecular disturbance. The continuous current however not only produces its chemical action at the poles, but this molecular disintegration and orientation is propagated throughout the zone between the poles. Just what the galvano-caustic action is that dissipates a tumor is not yet known—whether it coagulates the albuminoids or creates interstitial inflammation, Dr. Bigelow says he does not know; *it does reduce the tumor* and it remains for us to find out the *why*. He believes that time will demonstrate a change of *cell life* in addition to the purely chemical action, which takes place around the poles. In Apostoli's clinic the induced current is not often used. It has a wondrous effect, however, upon the ovarian pain in hysterical women. Dr. Bigelow has now seen twenty cases of this kind and every woman received immediate relief after a *séance* of ten to fifteen minutes. He has seen a large number of bleeding fibroids, but has as yet to see one that failed to respond immediately to the continuous current, the positive pole being within the uterus.

Apostoli often carries the current up to 350 milliamperes without any discomfort to the patient. It is most important that every part of the lining membrane of the uterus should be treated, and every hemorrhage, no matter how severe it may be, will resist. Dr. Bigelow affirmed that the treatment would also very appreciably diminish the size of fibroids and at times entirely dissipate them. He quoted cases to prove this point. Punctures were made into the tumors to the depth of from one to three centimeters, with a lance-pointed steel needle, the galvano-*negative* caustic being used, usually. Everything was religiously clean and antiseptic. None of the patients had any bad symptoms. He affirms that Apostoli's method arrests hemorrhage, diminishes size, relieves pain, and improves nutrition without endangering life, and does this better and more surely than any other

method; and he asks why then resort to Tait's operation of excision of the appendages?

The catarrhal forms of salpingitis yield kindly to the simple action of the continuous current, one pole in the uterus. Dr. Bigelow is not yet ready to offer any decided opinion in regard to pyo-salpingitis. He however cited several cases in which negative puncture of the tube relieved or cured the case. In metritis the galvanic or Faradic current should be used according as one or the other agrees with the patient. Apostoli says that "this treatment, applied according to his double or bi-polar method, is an excellent and sometimes sovereign remedy in certain cases (recent subinvolution, chronic metritis in its first stage); inefficacious, or at least very insufficient, in others (such as chronic metritis in its latter stages), and endometritis in any form." In endometritis the continuous current and the positive pole within the uterus are used. He cited some cases of fungoid endometritis which had been cured. Dr. Apostoli Faradized every woman, even when under an acute attack, who was suffering from peri-uterine inflammations, observing certain rules which he has laid down. In the subacute stage, he uses first bi-uterine Faradization with a current of tension. When the inflammation begins to give way he uses the intrauterine continuous current, beginning first with the positive pole and following with the negative as soon as he is sure that the patient can bear it. In the chronic stage he uses the continuous current and galvano-puncture (negative), making the puncture in the diseased part itself. In old cases of perimetritis with much tenderness around the utero-sacral ligaments, much relief may be obtained by the vaginal electrode in the posterior fornix, while the negative pole is on the abdomen, using the induced current of high tension.

Dr. Joseph Price read a paper on

A Year's Work in a Maternity Hospital.

In making this report I desire briefly to call attention to the amount of work done, the routine treatment of patients, and a few alterations which have taken place in the building. During the year 1888 there were 184 deliveries in the Preston Retreat. Of these patients, 69 were primiparæ. There were 186 children born, including two sets of twins; 9 of these infants were still-born; 102 were males, 84 were females. There were 13 forceps deliveries. Labor was induced in 2 cases in the eighth month, for, in one case, a contracted pelvis and in the other, the presence of a large uterine tumor. There have been no deaths of mothers in the Retreat for a period of nearly five years, furnishing a series of 540 deliveries without a death, the last death being from puerperal convulsions in a patient suffering from chronic Bright's disease, who had had convulsions in five previous labors. Since this death there has not been a case of puerperal septicæmia in the institution.

The great success attending the work of this Maternity is due to the strict enforcement of the law of cleanliness. Every thing and every body in the house is clean, and jealously kept so. This system was enforced by Dr. Goodell and has been carried out on the lines laid down by him. The routine treatment of patients is as follows: the patient on entering the house is given a hot soap bath, dressed in clean underclothing and given a clean bed in the waiting ward. If necessary a laxative is given and the bowels kept open during her waiting period. Thereafter, until her confinement, she is obliged to take at least two hot soap baths per week, and to wear clean clothes. She is allowed to do such light work about the house as the physician may deem advisable, and is encouraged to take as much open-air exercise as circumstances will permit. Every effort is made by the officers and *employees* of the institution to make it as cheerful and homelike as possible. When ready for the delivery room, the patient is again given a hot soap bath, and an enema and a vaginal injection of 1 to 2000 bichloride of mercury solution. She is clothed in clean night-robe and drawers and placed upon a new, clean, delivery bed. Scrupulous cleanliness is observed in all manipulations of the patient, and after delivery a second vaginal injection is given and a vaginal suppository of iodoform is introduced. The patient's person is carefully cleaned and all soiled clothing removed, the binder applied, a clean set of night clothes put on, and the patient placed in a new, clean bed in the ward. All of the soiled articles are immediately removed from the delivery room and a new bed made up for the next patient. The patients in the ward are carefully observed by the nurses, but no unnecessary handling or interference is indulged in. The patients remain in the ward until they are able to be up, when they are removed to the convalescent ward. As the ward is emptied, the beds are burned and all the bedding most

carefully cleansed. No soiled linen (as draw-sheets, diapers, napkins, or other articles of clothing) is allowed to remain in the ward; but when soiled it is immediately placed in a covered receptacle and removed from the ward and building. No sponges, wash-rags or absorbent cotton are used in the house. Corrosive jute supplies the place of these articles, being clean, soft, remarkably absorbent, and cheap; it is destroyed immediately after use. The pads used to absorb the lochia are also composed of jute and are likewise destroyed after use. The beds in the wards are of new straw. All discharges from the delivery room are immediately burned. All bedding soiled beyond cleansing or contaminated by purulent or specific discharges are likewise burned. In short, every effort is made to keep the house perfectly pure and sweet. The arrangement of the house permits of rotation in the use of the wards, so that a ward once emptied is not again used until three others have been filled. In the meantime it is most carefully and scrupulously cleaned and thrown open to the atmosphere. A similar system is pursued in the convalescent wards and delivery room.

A few alterations in the building have very markedly increased the effectiveness of the institution and the comfort of its inmates. In the first place, the bath-room and water-closets have been removed from the building proper and placed in the towers in the rear. The plumbing is as nearly perfect as modern sanitary science can make it. The verandas have been enclosed in glass, forming large, light, airy corridors about the rear of the building, and furnishing a distinct, circulating atmosphere between the house proper and the wards and the water-closets. The ventilation of the entire building is simply perfect. The capacity of the house at present is about 50 patients per month and, when a few contemplated changes are made, the capacity will be doubled and the institution rendered as nearly an ideal maternity hospital as is practicable.

Dr. Wm. Goodell said it had always been a matter of great regret to him that he did not adopt this system a year or a year and a half before he did. He supposed that his delay was partly due to the conservatism of old age and partly to a series of some 40 deaths from bichloride of mercury poisoning he had collected. Tarnier's reports of the results following the use of this agent so impressed him, that he was led to make the change. Before he adopted the system which has just been detailed by Dr. Price, he had once as many as five deaths in about 150 cases, four of these due to septicæmia. Latterly hardly a year would elapse without the occurrence of one or two deaths. When he first started everything about the institution was new and clean, and for several years he had the best record of any maternity hospital in the world. After the building and articles had become old, deaths began to occur. He tried carbolic acid, but it proved of little value. After beginning the use of corrosive sublimate injections, iodoform suppositories and antiseptic pads, he did not have a death from septicæmia. The only death was one from Bright's disease of the kidneys. During this time he had been consulted perhaps a dozen times in the course of a year to see women dying from puerperal septicæmia. He thought that in private practice it would not be needful to follow out so strictly the details of the method as it is practised at the Preston Retreat. For instance, the antiseptic pad and the iodoform suppositories might be done away with. He believed however that every practitioner should syringe out the vagina both before the birth of the child and after complete delivery, with a bichloride solution of 1-2000. The hands should also be disinfected. He was called in consultation by a physician in the country who had had four or five deaths from sepsis in a short time. Dr. Goodell found he had been treating a case of phlegmonous erysipelas. He knew of another physician who had lost, he thought, seven cases, certainly five, from dressing a sloughing case of erysipelas. Antiseptic measures would probably have saved all these cases.

Dr. Henry Leaman called the attention of those who have the opportunity of observing the physiological processes of labor to one point, viz.: presentation. It is very difficult to determine accurately the presentation, especially of the face, brow and posterior presentations. These observations should be verified by examination of the abdomen previous to labor and by the location of the fœtal heart sounds. They should also be confirmed by observation of the position of the head in the act of delivery. A mistake is readily made in posterior presentations. Posterior presentations are, he thinks, more frequent than we are in the habit of considering them. Every case of labor is a case for the minutest observation. There is another point which he thought should be observed, that is, the hour of the day at which labor occurs. There is probably some connection between

arterial pressure and the time of delivery. In recording the hour an allowance is to be observed in cases in which the forceps are used. There is another point not mentioned, and that is the position of the succedaneum and its extent. These have to do with the natural process of labor and aid in determining the presentation.

Dr. J. Price said he was as anxious about a labor as he was about a section. When he read reports of Maternity Hospitals with a mortality of from two to twenty-seven per cent., this troubled him not a little now that he controlled a large maternity hospital, one in which Dr. Goodell had left a record of 275 cases without a death. He sees a labor case as frequently as he does one of drainage after abdominal section. When this hospital was new, Dr. Goodell had a run of 250 cases without a death from any cause. This was the longest run of any institution at that time; after this deaths began to occur; later he adopted the gospel of cleanliness, and with what result he has just stated. The results are now precisely the same as he left them. In regard to Dr. Hirst's question as to whether the same results might not be obtained by simpler methods, Dr. Price said that they did not differ much in regard to the use of solutions and that portion of the treatment. The toilet of the house was perhaps just as systematically carried out at the Philadelphia Hospital as at other institutions. The pad which he had shown would hold a pint of fluid. It saved an immense amount of laundry work. It was now coming into use as a menstrual pad and was very convenient for women traveling. In private practice the mortality is greater among the rich than the poor. Among the poor he has had 700 deliveries without a death. He thought the difference was in the water-closets which the better classes have in their houses. The mortality throughout the country is large. In a small town in Ohio, with a high elevation and beautifully located, he had recently known of two deaths from septicæmia. Last summer he had been called to see puerperal cases nine times, and all the patients died.

—The Philadelphia Polyclinic has devised a scheme to accommodate physicians who are unable to leave home for a prolonged period. It now issues tickets, good in any department for one clinic weekly for three months, and at the usual fee for a six weeks' course of daily clinics. This should be a great convenience to practitioners residing within a day's journey of the city.

Reports of Clinics.

PHILADELPHIA HOSPITAL.

CLINIC ON DISEASES OF CHILDREN—DR. HIRST.

Method of Conducting Post-mortem Examinations of Infants.

Before beginning the *post-mortem* examination on the body of an infant that was three months old and was supposed to have died of congenital syphilis, Dr. Hirst remarked that the body should always be weighed first; he also said that the liver and spleen in congenital syphilis are not, as in health, one thirtieth and one three hundredth respectively of the whole weight, but bear a much larger ratio, the former reaching sometimes so large a ratio as one sixth of the whole body weight. There are certain anatomical peculiarities in an infant's body with which one should be acquainted. The bladder, sigmoid flexure, and vermiform appendix are much larger proportionally in infants, while the position of the stomach is vertical, thus rendering vomiting so easy as to be mere regurgitation.

Upon external examination of the child nothing noteworthy was found. On opening the abdomen, the spleen was found to be of normal size, as was also the liver, so that there proved to be far less ground for suspicion of congenital syphilis than had been looked for. The kidneys were, as usual, lobulated. The respiratory organs were examined from the mouth down, in order to detect a foreign body, as a curd of milk, in the trachea, if the child had during life inspired some solid substance. The lungs were healthy, thus excluding pneumonia, which is a very frequent cause of death in infants. The thymus gland was normal. Dr. Grawitz has reported two cases in which this gland was so enlarged as to choke the infant. The heart was normal. The ductus arteriosus was closed. Dr. Hirst has seen it open in an infant four weeks old, and again at the third month. The foramen ovale, which remains patulous for a few days in all cases, was found reduced to an opening the size of a pin. It is not rare to find an opening the size of a pin-hole at the site of the foramen ovale as late as the twelfth month. The dura mater being, as usual, adherent to the sutures, the cranium was hard to remove. A knife was passed down the coronal and sagittal sutures, and the frontal and parietal bones thus removed.

The brain was slightly congested, but not to a degree sufficient to have caused any serious symptoms.

Dr. Hirst thought that the cause of death in this child, which had had diarrhœa, was either an ulcerated condition of the mucous membrane of the large intestines or an inflammatory infiltration of their connective tissue, causing atrophy of the absorbent glands, which latter condition a microscopic examination would be necessary to show. He also referred to the common occurrence of *post-mortem* intussusception in young infants and remarked that the difference between *ante-* and *post-mortem* intussusceptions is that the latter are without signs of inflammation or congestion.

He regards sterilized milk as the great remedy to prevent diarrhœa in infants, and he has recently devised a cheap and efficient apparatus for its preparation.

CLINIC ON NERVOUS DISEASES—DR. F. X. DERCUM.

An Affection Allied to Myxœdema.

The first patient I bring before you is a woman, fifty years old. When first seen, twenty months ago, she was confined in bed and her arms were fixed. She complained then that the least movement gave her intense pain; and her face showed it. There was also noticed this tremendous swelling of the arms.

Her history shows nothing peculiar. She has been married and has had several children that were healthy. Two and a half years before coming here she noticed that her arms were swelling, and six months after pain in the right arm began to appear, along the nerve trunks. These pains were paroxysmal, lasting from two hours to several days. During the paroxysms the arms looked larger and lobulated. This appearance subsided as the pains left. In spite of tenderness over parts of the limbs, there existed areas of marked anæsthesia, which were found up to within a short time ago. Some anæsthesia still remains in the right arm and the left forearm. The trunk and leg on the right side were also anæsthetic in patches, associated with which there were peculiar pains Now there is some anæsthesia of the right side of the neck, but none has ever existed on the face. The visual fields are now contracted, especially on the right side. The tongue has suffered, as the organ of taste, and the sense of smell has likewise deteriorated. The hearing on the right side is not as good as formerly.

The question for us to decide is: whether the case is one of local dystrophy, dependent upon some organic disease, or some general disease of nutrition affecting the body as a whole. I am inclined to the latter opinion, on account of the enormous masses of flesh upon the back, right thigh and knee, which have a nodulated feeling.

Myxœdema has been suggested. In this disease there is usually swelling of the connective tissue in all parts of the body, especially in the face and hands. This is not the case here. The skin is especially affected with hypertrophy. There is also in this case an absence of the dryness and hardness, as in myxœdema proper, from a deficient innervation of the sweat-glands. Some discoloration has been present and there was noticed a change of nutrition affecting the tissues beneath the skin. This change, however, did not extend to the muscles, which are not enlarged, nor to the bones; but is found in the subcutaneous tissue, which is connective tissue. This is found out by introducing a Duchenne trochar and excising a small piece of tissue, which, under the microscope, is found to be largely mucous tissue and embryonal fat. The blood-vessels show an infiltration of their sheaths—a kind of sclerosis.

The nerve fibres—not the cerebro-spinal but the sympathetic—show a thickening of tissue and degeneration from inflammatory change, the connective tissue about the ganglia being much altered. Associated with these organic lesions, we must also bear in mind the curious pains and symptoms that we have mentioned.

It is not typical myxœdema, because the mental faculties are all right. It is true she is irritable, but no more than would be accounted for by her suffering. In myxœdema the thyroid gland undergoes lessening in size and marked change in structure. Here also we cannot feel the thyroid. In myxœdema there is hemorrhage from the mucous surfaces. Our patient has had hemorrhage from the throat, lungs and uterus. She has also vomited blood.

The prognosis in myxœdema is almost always unfavorable. One of the most favorable symptoms is great sweating. This woman at her worst did not sweat at all, but as she began to improve, the sweating commenced. She is not now getting any better. Her arms have increased an inch in circumference during the last six months.

As regards treatment, when the pain was

violent, she was given morphia. Now, as the pain is less, she is given antipyrin. Her general treatment has been tonic and symptomatic. She also has frequent cardiac dyspnœa, a symptom often found in myxœdema. This will be treated when necessary with cardiac sedatives.

UNIVERSITY HOSPITAL.

SURGICAL CLINIC.—PROF. D. HAYES AGNEW.

Fracture of the Clavicle.

This boy, eight years old, fell and fractured the right clavicle near the acromial end. Great care is to be used in the detection of such fractures in children, not only because they are less apt than adults to recognize them themselves, but also because they do not assume the position so characteristic in adults. This position consists in placing the forearm of the injured side across the chest and supporting it by holding the hand of the sound side beneath the elbow. The head also slightly inclines to the injured side. Children, too, also use their injured limbs remarkably well, because some fibres may not be broken, constituting a kind of green-stick fracture.

Fracture of the clavicle generally occurs, as in this case, near the acromial end, on account of the position of the curves and consequent distribution of force. The fragments in these fractures are more easily retained in position than if the fracture were at the sternal end.

In dressing such a fracture the loop of an adhesive strap is placed about the middle of the arm. Another adhesive strap, with a nick for the olecranon process, is placed beneath the elbow. The first is carried around the body behind and secured in position, not including the sound arm. The ends of the second piece are carried up over the shoulder of the sound side, one going in front of the chest and one behind it.

Pott's Disease.

This girl, eleven years old, has antero-posterior curvature of the spine, with a projection. She had worn a plaster-jacket for a year until a week ago, when she took it off as an experiment. Though the plaster-jacket interferes with development and should, therefore, be left off as soon as possible, yet as the reproduction of the disease would be such a serious matter, and as the reparative parts of the bone that have been thrown out are liable to injury because they are still spongy, it would be safer to keep it on for six months more.

Multiple Exostoses.

This girl, twenty-five years old, has many exostoses, occurring upon the tibia, knee, left angle of the scapula, and ribs. One near the upper end of the femur was so large as to interfere with locomotion and had to be removed. The wound is now healing satisfactorily. The patient never had rheumatism.

These exostoses began to develop about the age of puberty, when the epiphyses and diaphyses come together, and near the ends of the bones where the osteogenetic function is most active. They are true bone, and may begin from a slight inflammation of the periosteum.

New York Correspondence.

Prof. Winters on Constipation in Children.—Prof. Gibney on White Swelling and Pott's Disease.—Prof. Thomson on Jacksonian Epilepsy, Hammer Palsy, and the Treatment of Scarlet Fever, Typhoid Fever, and Diphtheria.—Dr. Holt on Chorea and Petit Mal.

New York, March 19, 1889.

Prof. J. E. Winters, in a recent clinic on constipation in infants, said that if the constipation is in a nursing infant, look first to the mother's bowels. If she is costive (has a daily but not a free and full movement), give her belladonna or ipecac, with small doses of strychnia, as the costiveness is probably due to diminished secretions in the alimentary canal. Follow these drugs with a cold, salt-water abdominal bath, kneading the abdomen thoroughly. If the mother is constipated (does not have daily movements), add some mild cathartic to the above treatment; cascara sagrada and the mineral waters are good. The diet should not be restricted but should consist of a plentiful supply of vegetables, fruits, and farinaceous food. Excessive tea drinking by the mother is sometimes the cause of colic and constipation in the infant. In such a case, discontinue the tea absolutely and use milk, chocolate, gruel, and coffee in moderation. If the cause does not lie in the mother, turn your attention to the child, and begin treatment with the juice of fruits; that of oranges is preferable, and a child two days old can take the juice of one-fourth of an orange, twice daily; and this amount should be increased daily. If this is not effectual try

grape juice, or the meats of stewed prunes and cherries. The latter are especially good. The cold, salt-water abdominal bath should be used for the mother in connection with this treatment of the infant. If it does not act, give an injection of glycerine (f℥ss-j) daily at a definite hour. It acts on the circulation and increases the secretion of the bowel. In addition to the injection, to every bottle of milk add a fluid drachm of glycerine, or a piece of fresh, unsalted butter as large as a hazel nut. Never use castor oil or rhubarb. If drugs are necessary, begin with a small dose of ipecac (gtt. ij-v), especially when the movements are hard and dry. Also use small doses of nux vomica and belladonna. If a cathartic becomes necessary, cascara sagrada is good. It does not lead to constipation and does not lose its effect by continual use. Begin with a small dose and increase it until there is a good movement daily, and then decrease it until it can be discontinued. Use fruit and glycerine injections with it. The use of opium by unscrupulous nurses and mothers is a frequent cause of constipation.

At a recent clinic by Prof. V. P. Gibney, at the New York Polyclinic and Hospital, the first case was one of caries of the ankle, a tubercular osteitis or, as it is commonly known, white swelling. The patient was a child 3 years old who, up to eight weeks ago, was perfectly well, though malnutrition and weakness were written on every line of her face. In walking she gave the characteristic ankle limp, directing attention immediately to the right ankle. Examination showed the presence of swelling, tenderness, atrophy of adjacent muscles, heat, and reflex spasm. The last symptom is important and characteristic of joint disease. The foot could be flexed, extended or rotated only a slight distance; beyond that, movement was opposed by muscular spasm. Palpation showed tenderness only at the epiphyses of the long bones, and Dr. Gibney thought the tarsus not involved. The lesion is a softening of the bone with the presence of tubercle, the process working from the centre to the periphery. Formerly, said Dr. Gibney, it was thought, and many surgeons still hold the same opinion, that there are only two ways of dealing with this disease, namely, by amputation or by excision; the diseased bone had to be gotten rid of. Dr. Gibney is decidedly opposed to operation and thinks the expectant plan of treatment the only plan upheld by results. For instance, he would treat this child in the following manner: pad the sole of the foot thickly with cotton, and put on a plaster bandage, running it well up the leg. By this means excessive weight is kept off of the ankle, and jarring is prevented by the cotton pad. Then give the child cod liver oil and iron, look after her general health, and get her out into the air and sunshine. When she is ten years of age she will have as good an ankle as anybody, and will be able to walk, skate, or dance. Let her go into most hospitals, however, and an operation will be performed that will not only maim her for life, but which, in most cases, will fail to stop the disease. In support of these statements he gave a synopsis of fifty or sixty cases, which were treated expectantly, and with brilliant results. This treatment refers to children, for, if the patient is an adult, it is useless to spend so much time. The proper course in adults is either to scoop out the diseased bone, amputate, or do excision.

The second patient was a boy, 15 years old, with well-marked Pott's disease of the dorsal region of the spine. He is being treated by fixation of the spine by means of a corset with two iron bars in the back, one on each side of the bony column. The disease, said the Professor, comes on usually between the age of two and eight years, seldom later than that. It attacks tubercular subjects, and the tuberculosis may be either congenital or acquired—acquired usually after a disease with a tardy convalescence. This gives good soil for the bacilli, which give evidence of their presence by means of a running ear, an eczematous head, or a phlyctenular conjunctivitis, the so-called "strumous condition." With such a condition a slight fall may start up the disease, or it may start without apparent cause. When deformity exists the disease is easy of diagnosis, and there is no excuse for mistake. It should be, however, diagnosticated early in its history, before there is any deformity. The following are some of the symptoms: pick the child up by its arms or chest and it cries; it moans in its sleep, tosses and is restless; its cry is very different from the sharp cry of hip disease; it walks peculiarly, with short, careful steps, holding the spine stiff; there may be associated spinal curvature, and if in the lumbar region, it will cause a hip-limp; the pain is a constant symptom, and if the disease is in the lumbar region the pain will radiate down the anterior crural nerve; if in the cervical region up the occipital nerve; while if the disease is in the dorsal region there will be gastralgia.

Dr. Gibney's treatment of spinal disease includes not only fixation, extension, etc., as the case may require, but also the internal use of the iodide of potassium, on the efficacy of which he lays great stress.

At a recent clinic by Prof. W. H. Thomson, at the University Medical College, the first patient exhibited was a child three years old, who, when eight months old, had had a fit. The spasm was confined chiefly to the left side, the eyes being turned to the right. It left the patient with paralysis of the left arm and leg, and a high fever lasting for two weeks. At irregular intervals since then, especially when cutting teeth, she has had similar fits, affecting the same side and giving the same manifestations. At night she clenches her hand and grinds her teeth. The convulsions and paralysis are epileptic, there probably having been a fall or some injury, with hemorrhage under the dura mater causing some thickening over the motor area. There is every indication of meningeal irritation over this area, and the implication of the eye shows that the irritation extends back to the angular gyrus or occipital lobe. If the fits recur, the case is just the kind that is suitable for the operation of trephining, for the removal of the hyperplasia. It is the kind of epilepsy called Jacksonian, and has these characteristics: that the fits always begin on the same side of the body, in the same muscles, and recur frequently. There being paralysis, and the fits being comparatively rare, the case might be mistaken for infantile paralysis, or anterior poliomyelitis. In the latter, there is a peculiar reaction to electricity. The Faradic current has no effect, while the galvanic or constant current causes contraction, both when the poles are applied and when the circuit is broken. This peculiarity indicates organic disease of the spinal motor centers, and is called the reaction of degeneration.

The next case was one of a rare disease called hammer palsy. The patient was a man, 53 years old, and a tinner, which occupation necessitated the continual use of a hammer. Four years ago, his right arm began to grow weak and to shake. His trouble increased, until now he has a well-defined case of palsy. Placing his feet together and shutting his eyes increase his tremor, but his body does not sway. An effort of the will to stop the tremors increases the shaking. There is no tremor of the tongue. There is great pain in the arm and leg. The palsy is one due to injury of the nerves from over-exertion and is similar to writers' palsy. The tremor being aggravated by the will excludes paralysis agitans.

The following is Prof. Thomson's treatment of scarlet fever:

℞ Acidi carbolici . . . . . gr. xvj
Bismuthi subnit. . . . . gr. xl
Pepsini sacch. . . . . gr. xl

M. Div. in pulv. viij. Sig. Take one every three hours.

This helps digestion and is antiseptic. Beef tea should be avoided and the diet consist only of milk. In the case of heart failure, heart stimulants must be used.

For other fevers, especially typhoid fever, he uses the following: Disinfect the alimentary canal with a calomel purge; a child three years old can take four grains. As soon as it acts use chlorine in the form of Labarraque's solution of chlorinated soda. Sweeten the milk and add this solution. A drachm can be given every half-hour if necessary. If the bowels are irritable use paregoric, etc.; but above everything else keep up the chlorine.

In diphtheria he uses Smith's solution of bromine, locally and internally, in some cases giving as much as a grain of bromine to a child one year old. When concentrated it produces strangury, hence it must be largely diluted. It does not cause vomiting as do the tincture of the chloride of iron and quinine. Diphtheria is a self-limiting disease, and all that a physician can do is to ward off complications. The greatest danger is septic poisoning, and Prof. Thomson thinks bromine the best remedy with which to avert this.

Dr. L. Emmet Holt, at one of his clinics on diseases of children at the Polyclinic, showed a case of chorea in a boy, which was interesting in showing the connection of chorea, heart disease and rheumatism. The patient's grandfather has heart disease; his father, heart disease and rheumatism; his brother, rheumatism; his sister, heart disease and rheumatism, and the patient himself chorea and heart disease. The boy had a phimosis, and he fell into the hands of a quack who operated upon him, giving the parents the assurance that the phimosis was the cause of the chorea and that upon its removal the chorea would disappear.

Another patient was a girl, 4 years old, whose parents have three other children in good health. When she was a year old she had eight or nine convulsions, and now, after an interval of nearly two years, they have returned. She falls; her face is pale, and the pallor is followed by cyanosis and

dilated pupils; there is loss of consciousness; her jaws are closed. The fits occur in the daytime, are of short duration, and are followed by a sound sleep. In her sleep she clenches her hand. It is a case of epilepsy, *petit mal*, and interesting from the fact that like many epilepsies it can be traced back to infantile convulsions. Epilepsy is often associated with rickets, but in this child the teeth appeared at the fourth month, she walked at the eighteenth, and there was no evidence of rickets. Dr. Holt's treatment was with the bromides; he prefers bromide of sodium, as it does not disturb the stomach and is pleasanter to take. When this can not be used, oxide of zinc, hyoscyamus, chloral and antipyrin can be tried. The treatment should be kept up at least a year and a half, and should include tonics.

PERISCOPE.

Diabetes and Tumors.

Dr. Tuffier has recently published a monograph on this somewhat important subject in the *Archives Générales de Médecine*. The coincidence of diabetes and neoplasms, only noted hitherto in a few scattered publications, and entirely overlooked in standard text-books, does not appear to be rare. This coincidence is not surprising to the author. He accepts M. Verneuil's bold theory that both tumors and diabetes are related to the arthritic diathesis. Already almost every form of tumor has been observed in diabetic patients. Almost every form of diabetes has been found to attack persons already the subjects of tumor. As a rule, the constitutional disease comes first; the patient is diabetic already before the tumor makes its appearance. Malignant tumors, as a rule, advance without causing much pain, and somewhat slowly in these cases, but they proceed more rapidly than the diabetic symptoms. They are apt to be taken for innocent growths. The complication in question is very serious in respect to operative interference, as we all know. No surgeon should think of removing small, innocent tumors which are causing no trouble. Dr. Tuffier describes two instructive cases. In the first, death occurred forty hours after the removal of a small parotid tumor. The fact that the patient was diabetic had been overlooked. This was also the case in the second example of the dangers of operation under the circumstances. "A little hypertrophic tumor of the skin of the cheek" was removed, at the patient's request. Phlegmonous erysipelas, followed by sloughing, set in and killed the patient within five days. Urgent operations must, Dr. Tuffier asserts, be undertaken with great caution. The safer are preferable to the most thorough, in his opinion. When an operation appears absolutely necessary, but not urgent, it is important to spend some time in reducing the diabetic symptoms by medical treatment. Should, however, all the sugar and polyuria disappear, the surgeon must still never overlook the nature of the patient's diathesis. Under the most favorable circumstances, in any case of that kind, deep operations and prolonged dissections, free division of vessels, and the formation of large flaps are to be avoided. The slow progress of tumors and the little pain which they produce are important facts, according to Dr. Tuffier. He has found that malignant tumors lie almost latent in diabetic subjects for a long period. Removal of a similar growth from a healthy subject would hardly insure him against so long an interval of time before recurrence. When an operation is thought advisable, the thermocautery is preferable to the knife. No attempt to insure union by first intention should be made if it involves the slightest traction on skin flaps. The wound must be laid open, but dressed with extreme antiseptic precautions.—*British Med. Journal*, Feb. 16, 1889.

The Formation of Hæmoglobin in the Spleen.

Dr. Krieuger, of Dorpat, has made a number of experiments on cats with the aid of Hüfner's spectro-photometer, for the purpose of discovering whether the amount of hæmoglobin contained in the splenic artery is greater than that in the splenic vein. He found that the quantity of blood in the splenic vein amounted to 9.52 per cent., while in the artery it was only 9.28 per cent. From these researches he came to the conclusion that hæmoglobin is actually formed in the spleen. The results are quite consistent with those obtained by different methods by Drs. Malassez and Picard in France and by Drs. Pashiutin and Vinogradoff in Russia. It is of course well known that there is a considerable quantity of iron in the tissue of the spleen, consequently there is no inherent improbability in Dr. Krieuger's theory.—*Lancet*, Feb. 16, 1889.

Nephrectomy for Floating Kidney.

Dr. W. Hager, of Wandsbek, in a paper published in the *Berliner klin. Wochenschrift*, Jan. 14, 1889, says that there is at present no subject in the whole of medicine upon which the opinions of authors differ so widely as upon the pathology and treatment of movable kidney. The explanation of this is found principally in the fact that the clinical pictures of floating kidney are so wonderfully different. While a degree of kidney dislocation may be borne in one woman with scarcely any discomfort, the same state of affairs will in others, for unexplained reasons, excite the most painful and serious symptoms.

The views in regard to the treatment of floating kidney differ still more widely than they do in regard to its pathology. While Keppler considered extirpation as the only possible cure, Landau and others reject every attempt at operative interference. For ordinary cases of floating kidney the bandage treatment is recommended by most authors. Dr. Hager, however, has been satisfied with it in only three out of the twenty-two cases in which he has used it. One of the patients had a protruding abdomen, and here the application of the bandage secured a highly satisfactory result, as it did also in a striking case of movable liver. Among the other cases, among which there were five nulliparæ, the bandages were very soon laid aside as useless, or even injurious In course of time, especially with careful regulation of the bowels, the discomfitures were lessened or the patients learned to become accustomed to them.

For the serious, though few, cases of floating kidney that require operation, there are two methods of operating :

1. Nephrectomy, first recommended by Keppler, of which, according to the latest statistics, there have been thirty-six cases, and 2. Nephroraphy after Hahn's method, which, according to the same statistics, has been performed in twenty-nine instances. The trial of both operations forces Lindner to the conclusion that in future he would rather himself assume the risk of nephrectomy than propose to his patients nephroraphy, an operation which is never entirely without danger and the results of which are so doubtful, as former experience proves. He further states that in nephrectomy when it is a success, patients are without exception freed from their sufferings.

To decide this very important question as to whether nephrectomy is, indeed, the only legitimate operation and, if it is a success, always leads to recovery, the report of the following case may be of weight.

Miss —— was in good health till August, 1886, when, while sea-bathing, she violently struck her abdomen, which pained her very much for a short time. In September her appetite became poor, and nausea, dizziness and at times, shortness of breath developed. Upon going to stool, the patient felt as though she were being drawn forward. She was considered chlorotic and iron and quinine prescribed. In December she suddenly had a violent attack, beginning with severe abdominal pain and general numbness, partial paralysis of the tongue and opisthotonus. Such attacks occurred two or three times a week, lasting several hours, and were accompanied with vomiting, nausea, and constipation ; there was also marked anemia and emaciation.

Upon April 20, Dr. Hager was summoned to the patient, and found her in an attack which, at first, appeared to be tetanus. There was agonizing pain in the epigastrium and opisthotonus. The attack lasted two hours. Examination the next day showed the heart and lungs to be normal, the epigastrium very tender, while the right kidney descended on deep inspiration. This movement was plainly perceptible ; the left kidney was normal. The urine, temperature and pulse were normal, so that only rest in bed and regulation of the bowels were ordered.

On April 27, a light kidney-shaped truss was ordered. A week afterward the patient was doing well, and then had a severe attack.

For a month all modes of bandaging were tried and failed, so that Dr. Hager felt forced to operate. He hesitated between nephrectomy and nephroraphy, and Dr. Wiesinger, of Hamburg, being called in, rejected nephroraphy as being at best uncertain and advised nephrectomy by Czerny's lateral incision, which operation he performed, tying the vessels with cat-gut ligatures. The wound was stuffed with iodoform lint and a bichloride dressing applied. The extirpated kidney was healthy. The pulse was fairly good after the operation. In the evening there were pain, vomiting and anuria ; the temperature was 97.7° F.

At three o'clock that night Dr. Hager found the patient apparently moribund from loss of blood, and, there being no bleeding vessel, he closed the wound with deep sutures, thus arresting the hemorrhage. The patient came to, June 6, passed a little urine and had great nausea. Both symptoms improved the next day. On June 7 a drainage

tube was introduced and the wound from that time improved rapidly, though the patient had continual desire to pass urine, which was dark, but contained no albumin and no abnormal constituents. On July 2 the wound was perfectly healed, and at the end of the month the patient could sit up in a chair for several hours.

On August 29 the patient was worse, and confined to bed with pain in the left side of the abdomen, dysuria, weakness and giddiness. Two weeks later Dr. Hager found that the left kidney was movable and that the patient had passed several stones. The urine was acid and free from albumin. On October 5, there had been pain and vomiting, but lately and during the last few weeks about fifty stones the size of a millet-seed were passed. Dr. Kummel now performed nephroraphy by Czerny's method and the patient returned home nearly well by the end of the month. After staying in bed and dieting ten weeks the patient could get up, and eight weeks afterward could walk about. The stones lessened under the use of Lithia water.

On Oct. 8, Dr. Hager was called to the patient and found her suffering with anuria of sixteen hours' duration, accompanied with headache, vomiting, and swelling in the left side, which was very tender and showed an area of dulness the size of one's hand. Uræmia being threatened, the propriety of establishing a urinary fistula was considered, but this proved to be unnecessary, as the flow of urine returned the next day. A dislocation of the kidney could not be demonstrated. It is nevertheless safe to assume that anuria, whether caused by a stone or acute angle in the ureter or kidney degeneration, will finally cause death from uræmia, especially since neither the family nor patient can be persuaded to consent to another operation.

The above case, he says, requires no further commentary, for there seems no doubt but that, in a previously healthy patient, dislocation and lithiasis in the left kidney are to be regarded as the results of the removal of its fellow organ.

He endorses Landau's opinion that in future no one will think of the extirpation of a sound kidney. Sometimes an operation will be indicated, and then only nephroraphy should be considered, which in most cases will prove satisfactory. Should there be a relapse, the operation, under antisepsis, may be repeated without danger. It will be of great importance to keep the patient in bed a long time with good regimen; for not unfrequently the symptoms of floating kidney have been seen to disappear for a long time without any operation under the use of Dr. Weir Mitchell's method of treatment.

Immediate Correction of Deformities from Hip-disease.

Dr. V. P. Gibney read a paper on the immediate correction of deformities resulting from hip disease before the New York Surgical Society, Oct. 24, 1888. In this paper, which is published in the *N. Y. Med. Journal*, Feb. 2, 1889, states that during the previous ten months he had employed the following treatment:

Under an anæsthetic, simple manual force is employed to pull the limb into position; the adductors and flexors are divided subcutaneously by means of the Adams fascia knife; the deeper flexors are cut by open incision; the femur is divided below the trochanter minor (Gant's operation); the plaster-of-Paris bandage is applied over a closely fitting stockingette or cheese-cloth bandage from the ankle to the free ribs; and rest in bed is required for a week or ten days.

He says he has made no attempt whatever to secure motion or to break up the adhesions. His aim has been to supplement the manual force with tenotomy, myotomy, or osteotomy—one, or all combined when necessary—and to secure parallelism of the limbs at one operation if possible. In many cases he states that the deformity has been so great and the resistance so obstinate that a second or third operation has been necessary to secure the object desired. The duration of the disease or the stage of deformity has not been taken into consideration. Where abscesses exist, or where numerous sinuses remain, he has freely opened the one and curetted the other.

The treatment subsequent to operation has been to continue the plaster-of-Paris dressing for a few weeks, and then to employ the long hip-splint for traction of the limb and protection of the joint. He asserts that in no single case upon which he has operated has any acute joint suppuration followed. Where abscesses or sinuses existed, the suppuration did not always cease; but the suppurative process has not been aggravated by the treatment employed. Friends of hospital patients have in a few instances complained that positive injury was inflicted. He gives in detail the histories of some of his cases.

Seventeen patients were between three and eight years of age, ten between eight

and twelve, and three were over twelve years of age. The disease had existed as follows: Six months in one case, one year in four cases, two years in three cases, three years in six, four years in four, five years in four, six years in five, seven years in two, and eight years in one case.

In four cases there was double hip-disease. In six cases Pott's disease also existed, and in one of these osteitis of the knee was likewise present. Ten cases presented deformity in a moderate degree, in eighteen the deformity was great, and in two it was extreme. He states that in only three cases the result has not been as good as was anticipated.

Professor Sée on Heart Diseases.

The Paris correspondent of the *Lancet*, Jan. 19, 1889, says that in resuming his winter course of lectures on clinical medicine, M. Germain Sée began by a general review of the diseases of the heart. Diseases of the heart, said the Professor, are not distinct from one another. It is the same affection presenting itself under different aspects, and offering different types. Whether the case be one of subacute or acute endocarditis, ulcerative or vegetating, the disease is always parasitic, and this view leads to a no less revolutionary deduction, that of the negation of their inflammatory nature. Under the latent, and sometimes the remote, influence of a specific disease, especially of articular or choreic rheumatism, the endocardium is exposed to the action of the microbe, easily defined in this part, although not so readily recognized in the joints. At other times the cause is a typhoid fever, or an attack of diphtheria long forgotten, scarlatina, infectious pneumonia, or even syphilis. There is no exception to this rule of the parasitic origin of valvular or myocardial mischief, except in chronic affections of the aortic orifice of old people, which coincide and result from the fatty, atheromatous, and sclerous changes of the arteries. Like all other cardiac diseases, those of the aortic orifice in the young are parasitic. It is degeneration without a trace of inflammation that is found in all heart lesions, whether acute or chronic, and to this condition Professor Sée would give the name of "*endocardie*." The same parts, the same elements, and the same spots are invaded, the permanent lesion consisting of a hyperplasia of the connective tissue. The disease is a continuation of the morbid process, which began in an acute or subacute form, perhaps unperceived by the patient or medical attendant. There is consequently but one cardiac disease, presenting two types—the endocardial and the valvular types. A third type is due to sclerous, atheromatous, and other changes in the arteries, comprised under the general term "arteritis," due to age, alcoholism, gout, diabetes, etc. The fourth type, and to which M. Sée assigns the most important place, is that condition of the heart which is caused by sclerosis of the coronary arteries, leading to degeneration and narrowing of the vessels, and ultimately to sclerosis of the myocardium—the fifth type. In the sixth class, Professor Sée places the hypertrophies and dilatations consequent upon primary valvular disease. The seventh class comprises the nervous troubles. Professor Sée does not think, however, that palpitation and acceleration of the heart's action ever leads to hypertrophy. A pulse of 140 may exist without producing this effect. Nor does exophthalmic goitre lead to the slightest lesion or fatigue. The eighth type is the pericardiac, the cause here being always parasitic. In the ninth and last category, come dilatation and aneurisms of the aorta.

Blennorrhœa in Women.

During the period of six years Horand has had under his care 5,090 women and 764 little girls suffering with blennorrhœa, and it is upon this large number of observations that he bases (*Lyon méd.*, 1888, lix, 251) the present study. He is a firm believer in the gonococcus as the cause of blennorrhœa, and teaches that where the gonococcus is not found there is no blennorrhœa. In the women the parts affected are, in order of frequency, the urethra, vagina, glands of Bartholin, uterus, and anus. In little girls the order is vagina, urethra, vulva, and anus. Urethral blennorrhœa in women causes little disturbance; it may give rise to slight itching or more frequent urination; cystitis is rare. It may continue a long time, months or years, and is apt to remain limited to the urethra. Inflammation of the vulva is rare in women, more frequent in girls. It is generally consequent upon mechanical irritation, want of care, direct contagion, attempts at rape, or is accidental from contact with objects soiled with blennorrhagic pus. It may exist alone or associated with elytritis or urethritis. The epithelium of the vestibule seems to offer a good deal of resistance to infection. Elytritis is more frequent—rather more so in girls than in women. Uterine blennorrhœa is very rare—

it was found only six times in four hundred and eighty-three examinations. It is the result of transmission from the vagina. Bartholin's glands are affected only secondarily. Anal blennorrhœa is more frequent in women than in men. It is the result both of mediate and of immediate contagion. Gonorrhœal rheumatism is very rare in women, as is gonorrhœal ophthalmia. For the treatment of urethritis the best means is nitrate of silver, a grain and a half to the ounce. For elytritis in a child, irrigations with a warm boric-acid solution of one-per-cent. strength should be used; in adults, the silver nitrate in stick applied directly every four or five days. The same treatment is also best for the disease when it affects the uterus, the anus, or the conjunctiva.—*N. Y. Med. Journal*, March 2, 1889.

Poisoning with Sulphocyanide of Mercury.

A patient was recently poisoned in Paris in a way that for some time remained undiscovered. The *Chemist and Druggist*, Feb. 14, gives the following explanation of it:

A sergeant, attached to the hospital, and chemically inclined, undertook one day to prepare Pharaoh's serpents' eggs. Being too much of a tyro to make the chemical himself, he purchased sulphocyanide of mercury from a dealer in town, and began to rub it to powder in a stone mortar in the hospital pharmacy. He was called away before finishing it, and, being unaware of the danger, left the stuff in the mortar. During his absence a nurse, sent, against the rules, by the sick officer for subnitrate of bismuth, took in lieu of it some of the sulphocyanide of mercury, which poisoned the patient, young De Carayon-Latour. As soon as trouble broke out, the sergeant threw away the contents of the mortar and said nothing. On investigation traces of a mercurial compound were found in the implement, and the cause of death was clearly traced to mercuric poisoning. But, as it was shown that the poison-closet had not been unlocked, it was impossible to conceive how the mercury could have been procured, until the sergeant confessed his fault. It may be interesting to note that the present is said to be the first instance of fatal poisoning by mercuric sulphocyanide recorded by French authors. An accident occurred in 1865 to a princely guest of one of the Paris hotels, who received immediate medical attendance, and speedily recovered. In the Carayon-Latour case, on the contrary, the patient, to save a comrade from punishment, concealed his state as long as he could, and received medical treatment too late to save his life. Considering the reckless use of the serpents' eggs by children and others, it must be conceded that the mercuric compound cannot be called a very violent poison. At the same time it cannot be considered the harmless insoluble combination that some pretend it to be. The treatment successfully resorted to in the older case was simple lime-water and reduced iron internally, and a warm poultice with laudanum on the abdomen. The next day the patient was well, and the voiding of a tapeworm, hitherto unsuspected, was the only reminder of the internal commotion caused by the sulphocyanide.

Syphilitic Disease of the Cervix Uteri.

Dr. E. Rode, of Christiania, has observed three cases of ulcerating gummata of the vaginal portion of the cervix. They appeared from ten to twelve years after infection. In all these cases there was extensive œdema of the pelvic connective tissue. Diagnosis was based upon the distinct history of syphilis, which was readily obtained from the patient. There were, moreover, no symptoms of local cancer, tuberculosis, or simple erosion. The patients all recovered rapidly after the administration of iodide of potassium. No local treatment beyond simple cleanliness was thought desirable. Dr. Rode's experiences are of considerable interest. A good monograph on the ulcers of the uterus, written by a recognized authority, would prove of great utility to practitioners and specialists. The nature of so-called "ulceration" of the cervix and its innocuous character have been proved. The "ulcer" is hardly even an erosion; it is rather the replacement of the natural squamous epithelium of the outer part of the cervix by a layer of the columnar epithelium proper to the cervical canal. The severe symptoms once attributed to "ulcerated womb" are due to totally different causes. Nevertheless, there are such things as ulcers of the cervix, due to cancer frequently, to syphilis occasionally, to tubercle rarely. The practitioner, recognizing the truth that a formidable-looking erosion is of little or no clinical import, must take care not to mistake an incipient true ulcer for that relatively harmless pathological condition.—*British Med. Journal*, Feb. 16, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.00
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All checks and postal orders should be drawn to order of

CHARLES W. DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE TREATMENT OF DIPHTHERIA.

Notwithstanding the fact that the treatment of diphtheria is a subject which has been so frequently discussed that medical men are in some danger of being confused by the variety of opinions expressed in regard to it, there can be no question of the advisability of calling attention to new communications which seem calculated to aid them in dealing with this formidable and unhappily common disorder.

In the *Berliner klinische Wochenschrift*, February 18, 1888, there is a paper by Dr. Arthur Hennig, of Königsberg, describing a plan for treating diphtheria which he has used in the enormous number of ten hundred and fifty-four cases, with the best results. One might hesitate to accept these figures as credible, were it not that the whole of Hennig's article bears the marks of great carefulness in statement, and that he distinctly declares that he includes under the head of diphtheria only well-pronounced cases, with actual diphtheritic membrane, and no cases of catarrhal diphtheria or diphtheritic catarrh, which are so often seen in families in which a case of real diphtheria has appeared.

Hennig regards diphtheria as primarily a local affection, and the constitutional disturbance as being in the nature of an intoxication from the products of the local disease. His treatment consists chiefly in applying ice-bladders to the neck and lime-water to the fauces. For the former he employs a suitable piece of the œsophagus of a steer, cleaned, filled with ice, wrapped in a napkin, and laid across the neck from ear to ear. Its application is kept up continuously—the ice being renewed when necessary—day and night until the patient finds the cold uncomfortable, and complains of chilliness, stiffness in the neck and a burning sensation in the larynx. When this occurs the ice-bladder has done its work. The most important parts of Hennig's recommendations in regard to the use of ice are that it should be used continuously, and that the application should always be dry, and never wet.

The use of lime-water is by gargling, when this can be done, or by taking a large quantity into the mouth and holding the head back and shaking it from side to side. In addition to this—or as a substitute for it—Hennig orders large quantities of lime-water to be swallowed, a tablespoonful or two at a time, and often enough to make up as much as three quarts in twenty-four hours. This amount has no ill effect upon the general system. The administration of lime-water is continued until the membrane disappears and the fauces are plainly healed.

To avoid the slight cauterant effect of the lime-water on the lips, they should be smeared with vaseline occasionally. When the diphtheritic process invades the nasal cavity, this is washed out every half-hour with lime-water. For this Hennig uses a small rubber ball, with an elastic tube attached. When lime-water cannot be applied to either the throat or the nose in any of the ways already mentioned, Hennig employs a spray-apparatus for the purpose.

In some cases of diphtheria Hennig uses a solution of chlorate of potash—one to three per cent.—giving the patient from a teaspoonful to a tablespoonful every two or three hours, according to age. He warns especially against using large quantities of this drug, or giving it at all, if the patient's heart is weak; and when it is to be given, he chooses a time after food has been taken. In regard to nourishment, Hennig recommends cold boiled milk, with from two to four egg-yolks stirred in it in the course of each twenty-four hours, when the appetite is deficient; and when the appetite is good he adds to the milk-diet clear soup, meat, and other solid food. He thinks it important to keep the bowels open with mild laxatives, and has no fear of heart failure from allowing a patient to be raised up to have a stool. Pain in the throat he treats with small pieces of ice, or moderate quantities of ice-cream. He permits his patients, if they feel like it, to get up, and allows children to be out of bed and to play, if they wish to, and adults to go about in the open air.

The plan of treatment described above is one which—aside from the large and fortunate experience of Hennig—commends itself to our judgment as rational and likely to be successful. Especially can we endorse his strong recommendation of the use of lime-water, as a safe and efficient remedy in diphtheria, and his methods of administering it. The writer of this Editorial has for years employed lime-water in the treatment of diphtheria, in adults, in children and in infants, in exactly the manner recommended by Hennig, with the most satisfactory results. We can also heartily endorse the other recommendations of Hennig, which are practical and sensible, and show plainly that he is an exceptionally careful observer of the needs of children, who furnish so large a proportion of the cases of diphtheria. Those who can read his whole paper will find in it details which we cannot now repeat, but which add materially to its value. Enough has been said, however, to give the readers of the REPORTER a clear idea of his method of treating diphtheria, and we trust they may find it helpful in their practice.

PICROTOXIN AS AN ANTIDOTE TO MORPHIA.

The discovery of a comparatively safe antidote to morphia would be a great gain to medical men, and it is interesting to learn that Prof. Arpad Bókai, of Klausenburg, in Hungary, thinks he has made such a discovery by experiments with picrotoxin. He finds that picrotoxin in small doses increases the activity of the respiratory centre in the medulla oblongata, and stimulates the vaso-motor centre. For these and other reasons he hopes that picrotoxin will prove to be a useful drug to administer in opium poisoning, as well as to prevent chloroform poisoning.

It does not appear from the abstract of his paper which is to be found in the *Wiener med. Presse*, Feb. 10, 1889, that he has experimented to prove the effects of picrotoxin after administering opium; but his expectations do not seem unreasonable, and it may be that some investigators in this country will undertake the work of determining how far they will be realized when put to the test. It would certainly seem worth while to do this, in view of the difficulties sometimes met with in treating cases of opium poisoning, and of the great advantage it would be to multiply our resources in such cases.

THE TREATMENT OF OZÆNA WITH GLYCERINE.

At a recent meeting of the Society of Military Surgeons in Vienna, Dr. Sidlo strongly recommended the treatment of ozæna with glycerine. His method consists in daily washing out the nasal cavity with a two per cent. solution of chloride of potassium, to which ten per cent. of glycerine has been added. This is followed up with the insertion of rolls of cotton soaked in a mixture of one part of glycerine and three parts of water, the tampons being allowed to remain in place for an hour at a time.

Using this method he claims good success in the management of ozæna. The method requires some weeks to effect a cure; but no one who has treated ozæna often will think a few weeks too long to devote to any method which is likely to be successful. The one proposed by Dr. Sidlo is so simple and apparently so rational that it certainly seems worthy of further trial, and if other medical men can cure such cases as he has cured in this way, it will be a very useful addition to our therapeutic resources.

THE AMERICAN PUBLIC HEALTH ASSOCIATION AND THE NEW YORK HERALD.

The Secretary of the American Public Health Association, has issued a circular calling attention to the fact that the Association has been made a victim of a deception by the *New York Herald*. It appears that, soon after the Milwaukee meeting of the Association, Mr. H. Lomb received a telegram, signed by James Gordon Bennett, asking for the Lomb Prize Essay on Sanitary and Economical Cooking for Persons of Small Means. It was thought desirable to publish it in the *New York Herald*, as that paper was believed to be a good medium for the presentation of this valuable essay to the public. Mr. Lomb and the Secretary went to New York to interview the representative of Mr. Bennett, who offered to purchase the essay. The offer was declined, but it was agreed to let the *Herald* have a copy of the essay and the privilege of being the first paper to present it to the public, with the understanding that it would be published in full. This proposition was accepted. But when it appeared, it was found that the *Herald* had disfigured it by various alterations and omissions, and by inserting unscientific and striking headlines. The result was to convert a useful scientific paper into a comparatively useless and sensational article. The American Public Health Association feels that it has been bitterly deceived, and that great injustice has been done to it as well as to the author of the essay. It seems that the Secretary appealed to the *New York Herald* to do the Association and the author of the essay justice; but he has so far received no reply. He has, therefore, issued a circular, stating these facts, and desiring the coöperation of medical journals to set the matter straight. We extend our sympathy to the American Public Health Association, and to all who may have been injured in this matter. But we cannot feel the surprise which the Secretary of the Association expressed at the way in which the *Herald* carried out its part of the bargain. Judging from the general and long established reputation of the *New York Herald*, it could hardly be expected to let slip an opportunity to amuse and entertain its readers out of consideration for the tender feelings of scientific men. But the occurrence will serve to enforce the lesson that those who have scientific matter to present to the public had better send it to legitimate scientific journals, and not to run the risk of falling into such a trap as this case seems to illustrate.

Relation of the Editor to the Advertiser.—In an Editorial in the New York *Medical Record*, March 23, the Editor states that a subject upon which he is frequently asked to advise the readers of the *Record* is one that concerns the reliability of advertisers and the relative merits of two or more

houses dealing in the same class of goods. He states further: "Attentive readers of this journal cannot have failed to perceive that the advertising department is distinct from the editorial department. The publishers exercise all possible care to accept advertisements from responsible parties only, and our readers must be content with this. The editor cannot personally endorse advertisers, nor can he undertake to decide upon the relative standing of two rival houses."

On turning the page on which these statements are made we find, at the conclusion of another editorial, the following: "In this connection we may refer to an article on 'Hydriodic Acid,' by Dr. William C. Wile (*Journal of the American Medical Association*). This writer speaks in high terms of hydriodic acid as a substitute of the iodides. He has used it successfully in chronic bronchitis, obesity, tertiary syphilis, chronic rheumatism, and in lead and mercurial poisoning."

The original paper of Dr. Wile in the *Journal of the Amer. Med. Association*, Jan. 26, 1889, concludes with the significant declaration: "It is scarcely necessary for me to state, that I have never used any other preparation than that of the originator of the unalterable syrup, of Mr. R. W. Gardner, of New York."

Turning now to the advertising pages of the *Record* we find that "Gardner's Syrup of Hydriodic Acid" occupies just half a page. It would perhaps be unkind to suppose that there is anything more than a mere coincidence in this association of publication; but it a rather singular coincidence.

—*Science*, Feb. 15, says that Dr. Schmelk of Christiania (*Centralblatt für Bacteriologie*) has found vast colonies of bacteria in the ice of the Jerstedalsbræ glacier and in the streams fed by it. They appear under the form of rods, and resemble the *Bacillus fluorescens liquefaciens*. During their period of growth these bacteria emit a fluorescent material. They multiply with great rapidity during periods of thaw.
